## A METHOD FOR CONTROLLING AN INTERNAL COMBUSTION ENGINE

### BACKGROUND AND SUMMARY

[0001] The invention relates to a method for controlling an internal combustion engine. The invention also relates to a computer program, a computer readable medium, a control unit, an internal combustion engine, and a vehicle.

[0002] The invention can be applied in heavy-duty vehicles, such as trucks, buses and construction equipment, such as wheel loaders, haulers and excavators. Although the invention will be described with respect to a truck, the invention is not restricted to this particular vehicle, but may also be used in other vehicles such as buses, construction equipment and passenger cars. The invention may also be used on other transportation means such as ships and boats.

[0003] For a vehicle internal combustion engine, such as a diesel type engine for a heavy-duty vehicle, an exhaust after treatment system (EATS) is usually provided to reduce emissions, e.g. of nitrogen oxides (NO<sub>x</sub>). Such a system, which may include units such as a selective catalytic reduction (SCR) converter, requires exhaust gas temperatures that are relatively high in order to provide an efficient emission reduction.

[0004] However, measures to reduce fuel consumption may reduce the heat loss from the engine to the EATS. Therefore, particularly at low load operation, cold ambient temperatures, and/or cold start events, the EATS might not get enough heat to operate efficiently.

[0005] US2015040560A1 discloses, for increasing the temperature in an EATS when cold starting an engine, an exhaust gas recirculation (EGR) pipe which is branched off at an exhaust gas manifold part assigned to an inactive cylinder group. The EGR pipe forces air to an intake manifold part assigned to an active cylinder group. Each cylinder group comprises an intake throttle, which is adapted to be separably operable. The air intake upstream of the active intake manifold is throttled to increase the forced air flow. Although this may provide some improvement in cold start situations, there is still a need to further increase EATS temperatures at low load operations.

[0006] It is desirable to reduce emissions from internal combustion engines. It is also desirable to improve the after treatment of exhaust gases from internal combustion engines at low load operations.

[0007] According to an aspect of the invention, a method is provided for controlling an internal combustion engine comprising at least one first cylinder and at least one second cylinder with respective reciprocating pistons, each of the first and second cylinders being arranged to receive air from a fresh air intake arrangement, to receive fuel, and to provide repetitive combustions by means of the received air and fuel, the method comprising

[0008] receiving in the first cylinder air from the fresh air intake arrangement,

[0009] expelling from the first cylinder gases in the form of the air received in the first cylinder or gases including at least a portion of the air received in the first cylinder,

[0010] guiding to the second cylinder gases expelled from the first cylinder,

[0011] injecting fuel into the second cylinder so as to provide repetitive combustions with air in the gases guided from the first cylinder to the second cylinder,

[0012] and, while guiding to the second cylinder gases expelled from the first cylinder, throttling or inhibiting the supply to the second cylinder of air from the fresh air intake arrangement,

[0013] wherein guiding to the second cylinder gases expelled from the first cylinder comprises guiding to the second cylinder all gases expelled from the first cylinder.

[0014] Receiving in the first cylinder air from the fresh air intake arrangement and guiding to the second cylinder gases expelled from the first cylinder provides for heating by pre-conditioning of the air. Throttling or inhibiting the supply to the second cylinder of air from the fresh air intake arrangement limits temperature reductions caused by introduction of fresh air.

[0015] In addition, guiding to the second cylinder all gases expelled from the first cylinder means that no gases introduced to the first cylinder will reach an exhaust after treatment system (EATS) arranged to receive exhaust gases from the engine, without passing the second cylinder. Thereby the mass flow through the engine may be substantially decreased, and a further significant increase of the temperature of gases reaching the EATS at low load operations, cold start events or low ambient temperatures may be provided. This will improve the after treatment of exhaust gases from the engine, e.g. at low load, and thereby engine emissions will be reduced.

[0016] Also, the second cylinder combustions per se may be controlled without consideration for keeping exhaust gas temperatures high. Therefore the emission reduction may be provided without having to compromise running the engine for an optimal fuel efficiency.

[0017] The invention may significantly improve exhaust after treatment processes of diesel engines at extended low load or idling operations, such as operations of asphalt laying vehicles, in queues or in city driving.

[0018] Preferably, expelling gases from the first cylinder comprises expelling from the first cylinder the same amount of air as received in the first cylinder. Thereby, fuel injection into the first cylinder may be terminated so as to avoid combustions therein. Nevertheless, the air may be heated by compression in the first cylinder. The method may comprise injecting fuel into the first cylinder so as to provide repetitive combustions with the air received in the first cylinder. Thereby, heating of the gases reaching the second cylinder may be increased by the combustion in the first cylinder, whereby the overall heating capacity of the process is increased.

[0019] The method may advantageously comprise switching between a first mode with no injection of fuel into the first cylinder, and a second mode with injection of fuel into the first cylinder so as to provide repetitive combustions with the air received in the first cylinder. It should be noted that preferably the amount of fuel injected into the first cylinder is smaller, preferably considerably smaller, than the amount of fuel injected into the second cylinder.

[0020] According to another aspect of the invention, a method is provided for controlling an internal combustion engine comprising at least one first cylinder and at least one second cylinder with respective reciprocating pistons, each of the first and second cylinders being arranged to receive air from a fresh air intake arrangement, to receive fuel, and to provide repetitive combustions by means of the received air and fuel, the method comprising

[0021] receiving in the first cylinder air from the fresh air intake arrangement,

[0022] expelling from the first cylinder gases in the form of the air received in the first cylinder or gases including at least a portion of the air received in the first cylinder,

[0023] guiding to the second cylinder gases expelled from the first cylinder,

[0024] injecting fuel into the second cylinder so as to provide repetitive combustions with air in the gases guided from the first cylinder to the second cylinder,

[0025] and, while guiding to the second cylinder gases expelled from the first cylinder, throttling or inhibiting the supply to the second cylinder of air from the fresh air intake arrangement,

[0026] the method further comprising injecting fuel into the first cylinder so as to provide repetitive combustions with the air received in the first cylinder.

[0027] As also suggested above, injecting fuel into the first cylinder so as to provide repetitive combustions with the air received in the first cylinder may advantageously increase heating of the gases reaching the second cylinder, whereby the overall heating capacity of the process is increased.

[0028] Preferably, where each of the first and second cylinders is arranged to receive air from the fresh air intake arrangement via first and second intake guides, respectively, expelling gases from the first cylinder is done by means of an exhaust guide extending from the first cylinder, e.g. to the atmosphere via an EATS, and guiding to the second cylinder gases expelled from the first cylinder comprises at least partly closing an exhaust valve in the exhaust guide. For example, guiding to the second cylinder gases expelled from the first cylinder may be done by means of a recirculation guide extending from the exhaust guide and to the second intake guide, and the exhaust valve may be provided downstream of the recirculation guide. The exhaust valve may effectively provide for selectively guiding a portion or all of the gases from the first cylinder into the recirculation guide.

[0029] Said exhaust guide may be referred to as a first exhaust guide. The expelling gases from the second cylinder may be done by means of a second exhaust guide extending from the second cylinder. Preferably, the first and second exhaust guides merge downstream of the exhaust valve.

[0030] Preferably a turbine of a turbo charger is located downstream of the exhaust valve. Thereby, such a location of the exhaust valve may secure that heat is not lost by expansion in the turbine before the gases reach the second cylinder. The exhaust valve may prevent a partial flow to the turbine, and secure that all gases expelled from the first cylinder are guiding to the second cylinder.

[0031] Preferably, where each of the first and second cylinders is arranged to receive air from the fresh air intake arrangement via first and second intake guides, respectively, at least one compressor is provided upstream of the first and second intake guides and downstream of the fresh air intake arrangement. Thereby, an advantageous arrangement of a single compressor service the two intake guide may be provided.

[0032] Preferably, where each of the first and second cylinders is arranged to receive air from the fresh air intake arrangement via first and second intake guides, respectively, the expelling of gases from the first cylinder is done by means of a first exhaust guide extending from the first cylinder, and guiding to the second cylinder gases expelled from the first cylinder is done by means of a recirculation guide extending from the first exhaust guide and to the

second intake guide, the method further comprises expelling from the second cylinder gases by means of a second exhaust guide extending from the second cylinder, e.g. to the atmosphere via an EATS, and recirculating gases from the first and second exhaust guides to the first and second cylinder by means of an exhaust gas recirculating (EGR) passage provided in addition to the recirculation guide.

[0033] Thus the recirculation guide may be provided in addition to the EGR passage. The recirculation guide may bypass the EGR passage. Thereby, the EGR passage may be used in a traditional manner, at most operational situations, and include an EGR cooler for reducing the temperature of recirculated exhaust gases. By the recirculation guide, the heating process described above, e.g. for low load operation, may be provided without interference or adverse effect of the EGR cooler. A valve may be provided to control and selectively inhibit gas flow through the EGR passage. It should be noted however, that the method may involve guiding gases through the EGR passage as well as through the recirculation guide.

[0034] The method may comprise compressing in the second cylinder the gases guided to the second cylinder, and injecting the fuel into the compressed gases. Thereby the method may be advantageously provided in an engine adapted for a diesel cycle.

[0035] According to another aspect of the invention, a method is provided for controlling an internal combustion engine comprising at least one first cylinder and at least one second cylinder with respective reciprocating pistons, first and second intake guides arranged to guide air from a fresh air intake arrangement to the first and second cylinders, respectively, an intake valve arrangement being arranged to control the provision of air to the second cylinder via the second intake guide, a fuel system arranged to inject fuel into the first and second cylinders, a first exhaust guide and a second exhaust guide arranged to guide gases from the first and second cylinders, respectively, towards an exhaust after treatment system, and a recirculation guide extending from the first exhaust guide to the second intake guide, the method comprising

[0036] allowing air from the fresh air intake arrangement to be received in the first cylinder,

[0037] allowing gases in the form of the air received in the first cylinder or gases including at least a portion of the air received in the first cylinder to be expelled from the first cylinder,

[0038] controlling an exhaust valve located in the first exhaust guide so as to reduce or inhibit the transport of gases from the first cylinder to the exhaust after treatment system and to guide to the second cylinder gases expelled from the first cylinder, and

[0039] simultaneously controlling the fuel system so as to inject fuel into the second cylinder, so as to provide repetitive, combustions with air in the gases guided to the second cylinder, and controlling the intake valve arrangement for throttling or inhibiting the supply to the second cylinder of air from the fresh air intake arrangement.

[0040] Similarly to as mentioned above, receiving in the first cylinder air from the fresh air intake arrangement and guiding to the second cylinder gases expelled from the first cylinder provides for heating by pre-conditioning of the air. Throttling or inhibiting the supply to the second cylinder of air from the fresh air intake arrangement limits temperature reductions caused by introduction of fresh air.

**[0041]** The exhaust valve may be at or downstream of the recirculation guide. The exhaust valve may effectively provide for selectively guiding a portion or all of the gases from the first cylinder into the recirculation guide. Thereby the amount of gases introduced to the first cylinder and reaching an EATS, without passing the second cylinder, may be selectively controlled. Thereby the mass flow through the engine may be effectively controlled.

**[0042]** Preferably the method comprises controlling the exhaust valve comprises controlling the exhaust valve so as to inhibit the transport of gases from the first cylinder to the exhaust after treatment system and to guide to the second cylinder all gases expelled from the first cylinder. By closing the exhaust valve, all gases introduced to the first cylinder may be guided to the second cylinder, and a significant increase of the temperature of gases reaching the EATS at low load operations, cold start events or low ambient temperatures may be provided.

**[0043]** Similarly to as described above, the method may comprise controlling the fuel system so as to inhibit injection of fuel into the air received in the first cylinder. The method may comprise by controlling the fuel system to inject fuel into the first cylinder so as to provide repetitive combustions with the air received in the first cylinder. Thereby, air remaining after first cylinder combustions and combustion products may be thoroughly mixed in the first cylinder and the first exhaust guide, ensuring a homogeneous gas mixture reaching the second cylinder. The amount of fuel injected for each combustion in the first cylinder is preferably smaller than the amount of fuel injected for each combustion in the second cylinder. Nevertheless, the first cylinder may contribute to a crankshaft torque of the engine.

**[0044]** Preferably, the method comprises controlling a ratio of air in the gases expelled from the first cylinder and guided to the second cylinder by controlling the amount of fuel injected into the first cylinder. Thereby, the amount of EGR gases in the second cylinder combustion processes may be controlled to a suitable level, e.g. for limiting NOx production in the second cylinder. The method may advantageously involve not recirculating any exhaust gases to the first cylinder. Thereby, the ratio of air, or the ratio of combustion products, also referred to as an EGR rate, in the gases expelled from the first cylinder and guided to the second cylinder, may be accurately calculated with the need for any sensor in the recirculation guide. This reduces the complexity of the engine, and also eliminates a problem of incorporating a sensor in a potentially harsh exhaust environment in the recirculation guide. Instead the EGR rate may be accurately calculated, e.g. based on the air intake boost temperature, the boost pressure, the volumetric efficiency and the amount of fuel injected into the first cylinder.

**[0045]** Preferably, where the intake valve arrangement comprises an intake divider valve, the second intake guide being arranged to receive air from the fresh air intake arrangement via the first intake guide, controlling the intake valve arrangement comprises at least partly closing the intake divider valve. Thereby the supply to the second cylinder of air from the fresh air intake may be inhibited by closing the intake divider valve. The intake divider valve may be provided e.g. as a flap or a throttle valve. Alternatively first and second throttle valves may be provided in the first and second intake guides, respectively, arranged to block a communication between the fresh air intake and the first and second cylinders, respectively. However, a single

intake divider valve may replace two such first and second throttle valves, whereby complexity and cost is reduced.

**[0046]** Advantageously, the method comprises determining the temperature of gases expelled from the second cylinder, wherein the control of the intake valve arrangement is made in dependence on the determined temperature of the gases expelled from the second cylinder. Thereby, an effective way of controlling the temperature of gases reaching an EATS is provided.

**[0047]** Preferably, the method comprises determining a load of the engine, wherein the control of the intake valve arrangement is made in dependence on the determined engine load. Thereby, a further effective way of controlling the temperature of gases reaching an EATS is provided. For example, as the engine load increases, the intake valve arrangement may be controlled so as to gradually increase the amount of air reaching the second cylinder without passing the first cylinder, so as to avoid exhaust temperatures becoming too high.

**[0048]** Preferably, where a recirculation valve is arranged to control the flow through the recirculation guide, the method comprises controlling the exhaust valve and the recirculation valve so as to terminate or reduce the guiding to the second cylinder of gases expelled from the first cylinder, and substantially simultaneously controlling the intake valve arrangement so as to increase the supply to the second cylinder of air from the fresh air intake arrangement. Thereby, a smooth change from the heat mode described above, with gas transport from the first to the second cylinder, to a normal engine mode with all cylinders operating similarly, may take place.

**[0049]** Further advantages and advantageous features of the invention are disclosed in the following description and in the dependent claims.

#### BRIEF DESCRIPTION OF THE DRAWINGS

**[0050]** With reference to the appended drawings, below follows a more detailed description of embodiments of the invention cited as examples.

**[0051]** In the drawings:

**[0052]** FIG. 1 is a side view of a truck comprising an internal combustion engine and an exhaust after treatment system.

**[0053]** FIG. 2 is a diagram of the engine and the exhaust after treatment system in the vehicle in FIG. 1.

**[0054]** FIG. 3 shows a block diagram depicting steps in a method according to an embodiment of the invention to control the engine in FIG. 2.

**[0055]** FIG. 4 shows a block diagram depicting steps in a method according to a further embodiment of the invention.

#### DETAILED DESCRIPTION

**[0056]** FIG. 1 shows a vehicle 1 in the form of a truck in a partly cut side view. The vehicle 1 has an internal combustion engine 2 for the propulsion of the vehicle 1.

**[0057]** As depicted in FIG. 2, the engine 2 comprises a plurality of cylinders, in this example six cylinders in an inline configuration. The cylinders are divided into a first cylinder group and a second cylinder group. The cylinders in the first cylinder group are herein referred to as first cylinders 201. The cylinders in the second cylinder group are herein referred to as second cylinders 202. In this example there are three first cylinders and three second cylinders. It

should be noted that the invention is equally applicable to engines with a different number of cylinder, e.g. two, three, seven, etc. Also, the number of cylinders in the first and second cylinder groups may be mutually different. In addition, the cylinder may have a configuration which different from an inline configuration, e.g. a V-configuration.

[0058] A control unit **601** is arranged to control devices in the engine **2** as described below.

[0059] The engine comprises a fuel system **801** arranged to inject fuel into the first and second cylinders **201**, **202** by means of fuel injectors **802**, each arranged to inject fuel directly into a respective of the cylinders **201**, **202**. The fuel injectors **802** are individually controllable by the control unit **601**.

[0060] The cylinders **201**, **202** are provided with pistons arranged to reciprocate in the cylinders. Each of the first and second cylinders **201**, **202** is arranged to receive air from a fresh air intake arrangement **303**. Thus, the cylinders are arranged to receive fuel, and to provide repetitive combustions by means of the received air and fuel. In this example, the engine is a diesel engine in which air received in the cylinders is compressed and fuel is injected into the compressed air.

[0061] The first and second cylinders **201**, **202** are arranged to receive the air from the fresh air intake arrangement **303** via an air conduit, and first and second intake guides **301**, **302**, respectively. The first and second intake guides **301**, **302** form together an air intake manifold. A first intake guide **301** and a second intake guide **302** are arranged to guide air to the first and second cylinders **201**, **202**, respectively, from a fresh air intake arrangement **303**.

[0062] An intake valve arrangement **304** is arranged to control the provision of air to the second cylinders **202** via the second intake guide **302**. The intake valve arrangement comprises an intake divider valve **304**, the second intake guide **302** being arranged to receive the air via the first intake guide **301**. The intake divider valve **304** divides the air intake manifold into the first and second intake guides **301**, **302**. The intake divider valve is controllable by the control unit **601**. The intake divider valve **304** is throttle valve. The intake divider valve **304** may be partly or fully closed to throttle or inhibit the supply to the second cylinder **202** of air from the fresh air intake arrangement **303**.

[0063] The engine **1** further comprises a first exhaust guide **401** and a second exhaust guide **402** arranged to guide gases from the first cylinders **201** and the second cylinders **202**, respectively, towards an exhaust after treatment system (EATS) **7** described below. A first exhaust valve **411** is provided in the first exhaust guide **401** and arranged to selectively reduce or inhibit a gas flow through the first exhaust guide **401** towards the EATS **7**. A second exhaust valve **412** is provided in the second exhaust guide **402** and arranged to selectively reduce or inhibit a gas flow through the second exhaust guide **402** towards the EATS **7**. The first and second exhaust valves **401**, **402** are controllable by the control unit **601**.

[0064] An exhaust gas recirculating (EGR) passage **404** is provided for recirculating gases from the first and second exhaust guides **401**, **402** to the first and second cylinder **201**, **202**. The EGR passage **404** presents two branches, each extending from one of the first and second exhaust guides **401**, **402** to a common EGR passage portion. A first and a second EGR valve **431**, **432** are arranged to control the flow through a respective of said EGR passage branches. The first

and a second EGR valves **431**, **432** are controllable by the control unit **601**. An EGR cooler **4041** is arranged to cool gases guided in the EGR passage **404**. A part of the EGR passage **404** is provided in the form of a venturi tube **4042**. The venturi tube **4042** may be provided with a pressure difference sensor, which may be used for determining the EGR flow.

[0065] A turbo charger **5** comprises a turbine **501** which is located downstream of the exhaust valves **411**, **412**, and is arranged to receive gases from the first and second exhaust guides **401**, **402**. The turbine is arranged to drive a compressor **502** which is provided upstream of the first and second intake guides **301**, **302** and downstream of the fresh air intake arrangement **303**.

[0066] A recirculation guide **403** extends from the first exhaust guide **401** to the second intake guide **302**. A recirculation valve **421**, controllable by the control unit **601**, is arranged to control the flow through the recirculation guide **403**. The recirculation guide **403** is advantageously used as described below.

[0067] The vehicle **1** also comprises an exhaust after treatment system **7** for treating exhaust gases from the engine **2**. The exhaust after treatment system **7** comprises an exhaust conduit **701** for conveying exhaust gases discharged from the engine **2**, as indicated by the arrow **702**. The exhaust after treatment system **7** further comprises a selective catalytic reduction (SCR) catalyst **705** provided in the exhaust conduit **701** for selectively reducing NOx contained in the exhaust gas. The exhaust after treatment system **7** further comprises means **711** for supplying a reductant, e.g. urea or ammonia, into the exhaust conduit **701** upstream of the SCR catalyst **705**, for the NOx reduction process in the SCR catalyst. The exhaust after treatment system **7** also comprises upstream of the SCR catalyst **705** and upstream of the reductant supply means **711** an oxidation catalyst (DOC) **714** having the function of oxidizing carbon monoxide (CO), hydrocarbons (HC) and nitrogen monoxide (NO) contained in the exhaust gases. The exhaust after treatment system **7** further comprises a diesel particulate filter (DPF) **716** disposed downstream of the DOC **714** and upstream of the injector **713** for capturing and collecting particulate matter contained in exhaust gas.

[0068] The control unit **601** is arranged to determine the exhaust gas temperature by means of a temperature sensor **602** arranged to detect the temperature in the exhaust conduit **701**.

[0069] Reference is made to FIG. **3** depicting steps in a method according to an embodiment of the invention to control the engine **2**. During operational conditions in which the temperature of the exhaust gases from the engine are high enough for the EATS to work efficiently, air is guided from the fresh air intake arrangement **303** to all cylinders **201**, **202**, in which fuel is provided so as for all cylinders to contribute to a torque of a crankshaft of the engine.

[0070] When conditions are such that the temperature of the exhaust gases from the engine are not high enough for the EATS to work efficiently, e.g. during a cold start event, or extended idling or low load situations, the engine is controlled as follows:

[0071] Air from the fresh air intake arrangement **303** is allowed S1 to the first cylinders **201**. The fuel system **801** is controlled so that no fuel is injected S2 by the fuel injectors for the first cylinders **201**. Thereby, all air received in the

first cylinders **201** will be expelled from the first cylinders into the first exhaust guide **401**.

[0072] The recirculation valve **421** is controlled **S3** to be open and the first exhaust valve **411** is controlled **S4** to be closed. The second exhaust valve **412** is controlled to be open. Thereby, the transport of gases from the first cylinder **201** to the EATS **7** is inhibited and all gases expelled from the first cylinder **201** are guided to the second cylinder **202** via the recirculation guide **403**. It should be noted that it is alternatively possible to throttle the first exhaust guide flow through the first exhaust valve **411** so that only a portion of the gases from the first cylinders **201** are guided through the recirculation guide **403**.

[0073] Simultaneously, the fuel system **801** is controlled **S5** so as to inject fuel into the second cylinders **202**, so as to provide repetitive combustions with air in the gases guided to the second cylinders **202** from the first cylinders **201**. Thereby, the intake divider valve **304** is controlled so as to inhibit **S6** the supply to the second cylinders **202** of air from the fresh air intake arrangement **303**. Thereby all gases received in the second cylinders **202** are guided from the first cylinders **201**.

[0074] Exhaust gases from the second cylinders **202**, provided with a high temperature due to said recirculation and said inhibition of the introduction of fresh air to the second cylinders **202**, are guided to the EATS via the second exhaust guide **402** and the turbine **501**.

[0075] The control unit **601** is arranged to determine **S7** whether exhaust gas recirculation (EGR), during the use of the recirculation guide **403**, should be requested, e.g. to reduce NO<sub>x</sub> production in the second cylinders **202**. If EGR is requested, the steps **S8-S14** described below may be carried out continuously or repetitively.

[0076] The amount of fuel to be injected into the first cylinders **201** is determined **S8** based on the air mass flow from the air intake arrangement **303** and a desired EGR ratio, i.e. a ratio air, or a ratio of combustion products, in the gases expelled from the first cylinders **201** and guided to the second cylinders **202**. The air mass flow may be determined based on the pressure in the first intake guide **301**, e.g. determined by means of a pressure sensor (not shown) in the first intake guide **301**, based on the temperature in the first intake guide **301**, e.g. determined by means of a temperature sensor (not shown) in the first intake guide **301**, and based on the volumetric efficiency of the engine. The fuel system **801** is controlled inject **S9** fuel according to the determined fuel amount into the first cylinders **201** so as to provide repetitive combustions with the air received in the first cylinders **201**.

[0077] Thus, method comprises controlling, by continuously or repeatedly adjusting **S8**, **S9** the amount of fuel injected into the first cylinders **201**, the EGR ratio by controlling the ratio of air, or the ratio of combustion products, in the gases expelled from the first cylinders **201** and guided to the second cylinders **202**.

[0078] In this example combustions in the first cylinder are compression ignited in a diesel cycle manner. The amount of fuel injected for each combustion in the first cylinders **201** may be smaller than the amount of fuel injected for each combustion in the second cylinders **202**. It is understood that the gases expelled from the first cylinders **201** comprise some combustion products as well as air not consumed by the combustions in the first cylinders.

[0079] By means of the temperature sensor **602** (FIG. 2) the exhaust gas temperature is continuously or repeatedly determined **S10**. In dependence of the determined exhaust gas temperature it is determined **S11** whether to adjust the intake divider valve **304** so as to throttle the fresh air supply to the second cylinders **202**, and thereby allow fresh air supply to the second cylinders **202**. By opening the intake divider valve **304** the exhaust temperature may be reduced if desired.

[0080] The method further comprises continuously or repeatedly determining **S12** a load of the engine **2**. This may be done as is known per se, e.g. based on the air mass flow from the air intake arrangement **303**, the amount of fuel injected into the cylinders **201**, **202** and the rotational speed of the engine. Based on the determine engine load, it is determined **S13** whether to adjust the intake divider valve **304** so as to throttle the fresh air supply to the second cylinders **202**, and thereby allow fresh air supply to the second cylinders **202**. If the engine load increases it may be desired to allow fresh air the second cylinders to decrease the exhaust temperature, and/or to allow a further increase of the engine load.

[0081] Where it is determined **S14** to allow the engine to operate in a normal mode with all cylinders participating equally in the crankshaft torque production, the first exhaust valve **411** is opened, the recirculation valve **421** is closed **S16**, and the intake divider valve **304** is opened **S15**.

[0082] Reference is made to FIG. 4. In a further embodiment the engine **2** is controlled as follows. Air from the fresh air intake arrangement **303** is allowed **S1** to the first cylinders **201**. The recirculation valve **421** is controlled **S3** to be open and the first exhaust valve **411** is controlled **S4** to be closed. The second exhaust valve **412** is controlled to be open. Simultaneously, the fuel system **801** is controlled **S5** so as to inject fuel into the second cylinders **202**, so as to provide repetitive combustions with air in the gases guided to the second cylinders **202** from the first cylinders **201**. Thereby, the intake divider valve **304** is controlled so as to inhibit **S6** the supply to the second cylinders **202** of air from the fresh air intake arrangement **303**.

[0083] It is to be understood that the present invention is not limited to the embodiments described above and illustrated in the drawings; rather, the skilled person will recognize that many changes and modifications may be made within the scope of the appended claims.

1. A method for controlling an internal combustion engine comprising at least one first cylinder and at least one second cylinder with respective reciprocating pistons, first and second intake guides arranged to guide air from a fresh air intake arrangement to the first and second cylinders, respectively, an intake valve arrangement being arranged to control the provision of air to the second cylinder via the second intake guide, a fuel system arranged to inject fuel into the first and second cylinders, a first exhaust guide and a second exhaust guide arranged to guide gases from the first and second cylinders, respectively, towards an exhaust after treatment system, and a recirculation guide extending from the first exhaust guide to the second intake guide the method comprising

allowing air from the fresh air intake arrangement to be received in the first cylinder,

allowing gases in the form of the air received in the first cylinder or gases including at least a portion of the air received in the first cylinder to be expelled from the first cylinder,

controlling an exhaust valve located in the first exhaust guide so as to reduce or inhibit the transport of gases from the first cylinder to the exhaust after treatment system and to guide to the second cylinder gases expelled from the first cylinder, and

simultaneously controlling the fuel system so as to inject fuel into the second cylinder, so as to provide repetitive combustions with air in the gases guided to the second cylinder, and controlling the intake valve arrangement for throttling or inhibiting the supply to the second cylinder of air from the fresh air intake arrangement, comprising determining the temperature of gases expelled from the second cylinder, wherein the control of the intake valve arrangement is made in dependence on the determined temperature of the gases expelled from the second cylinder.

2. A method according to claim 1, characterized by comprising controlling the fuel system so as to inhibit injection of fuel into the air received in the first cylinder.

3. A method according to claim 1, comprising controlling the fuel system to inject fuel into the first cylinder so as to provide repetitive combustions with the air received in the first cylinder.

4. A method according to claim 3, comprising controlling a ratio of air in the gases expelled from the first cylinder and guided to the second cylinder by controlling the amount of fuel injected into the first cylinder.

5. A method according to claim 1, wherein the intake valve arrangement comprises an intake divider valve, the second intake guide being arranged to receive air from the fresh air intake arrangement via the first intake guide

wherein controlling the intake valve arrangement comprises at least partly closing the intake divider valve.

6. A method according to claim 1, comprising determining a load of the engine, wherein the control of the intake valve arrangement is made in dependence on the determined engine load.

7. A method according to claim 1, where a recirculation valve is arranged to control the flow through the recirculation guide, comprising controlling the exhaust valve and the recirculation valve so as to terminate or reduce the guiding to the second cylinder of gases expelled from the first cylinder, and substantially simultaneously controlling the intake valve arrangement so as to increase the supply to the second cylinder of air from the fresh air intake arrangement.

8. A method according to claim 1, wherein a turbine of a turbo charger is located downstream of the exhaust valve.

9. A method according to claim 1, comprising recirculating gases from the first and second exhaust guides to the first and second cylinder by means of an exhaust gas recirculating (EGR) passage provided in addition to the recirculation guide.

10. A method according to claim 1, wherein the engine is adapted for a diesel cycle.

11. A computer comprising a computer program for performing the steps of claim 1 when the program is run on the computer.

12. A non-transitory computer readable medium carrying a computer program for performing the steps of claim 1 when the program product is run on a computer.

13. A control unit configured to perform the steps of the method according to claim 1.

14. An internal combustion engine comprising a control unit according to claim 13.

15. A vehicle comprising an engine according to claim 14.
