TOUCH-SENSING PANEL AND FORCE
DETECTION

RELATED APPLICATIONS

This application is a continuation of U.S. patent application Ser. No. 16/129,863, filed Sep. 13, 2018, which is a divisional of U.S. patent application Ser. No. 14/981,510, filed Dec. 28, 2015, now U.S. Pat. No. 10,146,351, which is a continuation of U.S. patent application Ser. No. 12/959,166, filed Dec. 2, 2010, now U.S. Pat. No. 9,223,445, all of which are incorporated herein by reference.

BACKGROUND

A position sensor can detect the presence and location of a touch by a finger or by an object, such as a stylus, within an area of an external interface of the position sensor. In a touch sensitive display application, the position sensor enables, in some circumstances, direct interaction with information displayed on the screen rather than indirectly via a mouse or touchpad. Position sensors can be attached to or provided as part of devices with a display. Examples of displays include, but are not limited to, computers, personal digital assistants (PDAs), satellite navigation devices, mobile telephones, portable media, players, portable game consoles, public information kiosks, and point of sale systems. Position sensors have also been used as control panels on various appliances.

There are a number of different types of position sensors. Examples include, but are not limited to, resistive touch screens, surface acoustic wave touch screens, capacitive touch screens, and the like. A capacitive touch screen, for example, may include an insulator coated with a transparent conductor in a particular pattern. When an object, such as a finger or a stylus, touches the surface of the screen there is a change in capacitance. This change in capacitance is sent to a controller for processing to determine the position where the touch occurred.

In a mutual capacitance configuration, for example, an array of conductive drive electrodes or lines and conductive sense electrodes or lines can be used to form a touch screen having capacitive nodes. A node may be formed at each intersection of a drive electrode and a sense electrode. The electrodes cross at the intersections but are separated by an insulator so as to not make electrical contact. In this way, the sense electrodes are capacitively coupled with the drive electrodes at the intersection nodes. A pulsed or alternating voltage applied on a drive electrode will therefore induce a charge on the sense electrodes that intersect with the drive electrode. The amount of induced charge is susceptible to external influence, such as from the proximity of a nearby finger. When an object approaches the surface of the screen, the capacitance change at every individual node on the grid can be measured to determine the location or position of the object.

SUMMARY

Disclosed are various examples of a touch sensor that includes exemplary force detection circuitry. The force detection circuitry can be used to determine an amount of force applied to the sensor.

BRIEF DESCRIPTION OF THE FIGURES

The figures depict one or more implementations in accordance with the present teachings, by way of example only,

2

not by way of limitation. In the figures, like reference numerals refer to the same or similar elements.

FIG. 1 illustrates schematically a cross-sectional view of a touch sensitive panel;

FIG. 2 illustrates schematically a plan view of conductors of the touch sensitive position-sensing panel of FIG. 1 together with a controller of a touch sensitive panel;

FIG. 3 is a circuit diagram of a first example of a force sensor useable together with the controller of a touch sensor;

FIG. 4 is a circuit diagram of a second example of a force sensor useable together with the controller of a touch sensor; and

FIG. 5 is a circuit diagram of a third example of a force sensor useable together with a controller of a touch sensor.

DETAILED DESCRIPTION

In the following detailed description, numerous specific details are set forth by way of examples in order to explain the relevant teachings. In order to avoid unnecessarily obscuring aspects of the present teachings, those methods, procedures, components, and/or circuitry that are well-known to one of ordinary skill in the art have been described at a relatively high level.

Reference now is made in detail to the examples illustrated in the accompanying figures and discussed below.

A display may be overlaid with a touch position-sensing panel, to implement a touch sensitive display device. The display may include various forms. Examples include, but are not limited to liquid crystal displays such as an active matrix liquid crystal display, an electroluminescent display, an electrophoretic display, a plasma display, cathode-ray display, an OLED display, or the like. It will be appreciated that light emitted from the display should be able to pass through the position-sensing panel with minimal absorption or obstruction.

FIG. 1 illustrates an exemplary touch position-sensing panel 1 which overlies a display 2. Although the force sensing may be used in touch sensors implementing other types of touch sensing, for discussion purposes, the drawing shows an example of a structure that may be used to implement a mutual capacitance type touch sensitive panel.

In the illustrated example, the panel 1 includes a substrate 3 having a surface on each side. The panel 1 includes a first number of electrodes 4(X) and a second number of electrodes 5(Y) provided on the opposite surfaces of the substrate 3. The substrate 3 is also provided adjacent to the display 2 such that one electrode 4(X) is between the display 2 and the substrate 3. An air gap is formed between the display 2 and the first electrode 4(X). A transparent adhesive layer 6 is between the second electrode 5(Y) and a transparent covering sheet 7.

In other examples, the touch position-sensing panel 1 may have a second substrate (not shown). With a second substrate, a touch position-sensing panel may have a transparent panel, a first adhesive layer on the panel, a first electrode layer forming first electrodes, a first substrate, a second adhesive layer, a second electrode layer forming second electrodes, and the second substrate. In such an example, the first conductive electrode layer is attached to the first substrate and the second conductive electrode layer is attached to the second substrate.

Returning to the illustrated example of FIG. 1, substrate 3, which forms a core of the exemplary touch sensitive position-sensing panel 1, can be formed from a transparent, non-conductive material such as glass or a plastic. Examples of suitable plastic substrate materials include, but are not

limited to Polyethylene terephthalate (PET), Polyethylene Naphthalate (PEN), or polycarbonate (PC).

In the mutual capacitance example, electrodes **4(X)** are drive electrodes provided on one surface of the substrate **3**, and electrodes **5(Y)** are sense electrodes provided on the opposing surface of the substrate **3**. Capacitive sensing channels are formed at the capacitive coupling nodes which exist in the localized regions surrounding where the first and second electrodes **4(X)** and **5(Y)** cross over each other and are separated by the non-conductive substrate **3**.

Transparent covering sheet **7** is provided over the substrate **3** and electrodes **5(Y)** and may be joined thereto using various methods and materials. One exemplary implementation is a pressure-sensitive adhesive. In one example, the covering sheet **7** may be glass, polycarbonate, or PMMA.

Indium-tin-oxide (ITO) is an example of a clear conductive material that can be used so form either one or both sets of electrodes **4(X)** and **5(Y)** in the example of FIG. **1**. Alternatively, any other clear conductive material may be used, such as other inorganic and organic conductive materials, such as Antimony-tin-oxide (ATO), tin oxide, PEDOT or other conductive polymers, carbon nanotube or metal nanowire impregnated materials, and the like. Further, opaque metal conductors may be used such as a conductive mesh, which may be of copper, silver or other conductive materials.

With reference to FIG. **2**, drive electrodes **4(X)** and sense electrodes **5(Y)** are formed by solid areas of ITO. Sensing area **10** of the position sensing panel **1**, denoted by the dotted line in FIG. **2**, encompasses a number of the intersections **11** formed by the drive electrodes **4(X)** and sense electrodes **5(Y)**. In the example, the gaps between adjacent X electrode bars are made narrow. This may enhance the ability of the electrodes **4(X)** to shield against noise arising from the underlying display **2** shown in FIG. **1**. In some examples, 90% or more of the sensing area **10** is covered by ITO. In an example like that shown in FIG. **2**, the gap between adjacent drive electrodes **4(X)** may be 200 microns or less.

In one example, each drive electrode **4(X)** forms channels with a number of the sense electrodes **5(Y)** on an adjacent plane. As mentioned previously, there are intersections **11** where the drive electrodes **4(X)** cross over the sense electrodes **5(Y)**.

A drive electrode connecting line **12** is in communication with a respective drive electrode **4(X)**. A sense electrode connecting line **13** is in communication with a respective sense electrode **5(Y)**. The patterns of the connecting lines are shown by way of an example only. The drive electrode connecting lines **12** and the sense electrode connecting lines **13** are connected to a control unit **20**.

In some examples, the change in capacitance at the node formed at each intersection **11** of drive electrode **4(X)** and sense electrode **5(Y)** when an object touches the surface of the panel **1** can be sensed by the control unit **20**. The control unit **20** applies pulsed or alternating voltages to the drive electrodes **4(X)** through the drive electrode connecting lines **12**. The control unit **20** measures the amount of charge induced on the sense electrodes **5(Y)** through the sense electrode connecting lines **13**. The control unit **20** determines that a touch has occurred and the location of the touch based upon the changes in capacitance sensed at one or more of the nodes **11**.

In some examples, the amount of charge induced on a sense electrode **5(Y)** can be measured by a current integrator circuit **22** incorporated in the control unit **20**. The current integrator circuit **22** can measure the accumulated charge on a capacitor at fixed time intervals. The exemplary controller

20 includes a number “n” of current integrators **22 a**, **22 b**, . . . **22n** and a processor **23**. Some of these integrators are used in the processing of signals from the sensing channels to detect touch on the touch position-sensing panel **1**.

Some touch sensor applications may take advantage of a measurement of the amount of force applied to the touch position-sensing panel **1**. For such an application of the touch sensor, a force sensor can be associated with the touch position-sensing panel **1** and controller **20**. The force sensor, in some examples, measures the amount of force applied to the transparent covering sheet **7** of the touch position-sensing panel **1**. The force sensor may be used to quantify or distinguish between different types of touch events. For example, the force sensor can measure the amount of force applied and cause the execution of a first function if the force is below or equal to a threshold. The force sensor can also measure the amount of force applied and cause the execution of a second function if the force exceeds the threshold.

With reference back to FIG. **1**, a resistive force sensitive element **30** can be used to measure the amount of force applied to the panel. In one example, the resistive force sensitive element **30** can be arranged between the touch position-sensing panel **1** and a supporting structure (not shown). In another example, the touch position-sensing panel **1** is incorporated in a portable device with the resistive force sensitive element **30** arranged between the touch position-sensing panel **1** and a housing of the device.

The resistive force sensitive element **30**, for example, may be formed of a Quantum Tunneling Composite material (QTC). The DC resistance of the QTC material varies in relation to applied force. In one example, the force sensitive element **30** can be formed by printing an ink containing the QTC material.

With reference back to FIG. **2**, in some examples, the resistive force sensitive element **30** can modulate the flow of current into a current integrator circuit **22** of the control unit **20**. The control unit **20** can include one or more current integrator circuits **22** that are not used in touch sensing operations. One exemplary controller **20** is the mXT224 sold by Atmel Corporation, of San Jose Calif. Using such a controller **20** facilitates force sensing by using existing circuitry of the control unit **20**. Thus, force sensing can be achieved, in some examples, without any additional dedicated electronic conditioning circuitry such as bias networks, amplifiers, analogue to digital converters, and the like.

With reference to FIG. **3**, a first exemplary circuit **32** that includes a resistive force sensitive element **30** is shown and described. The circuit **32** is in communication with an input of a current integrator **22** of the control unit **20**. The control unit **20** is connected to a ground rail **19** and a fixed voltage supply rail **27** that has a voltage V_{dd} . A resistive force sensitive element **30** having a value R_Q is connected between the fixed voltage supply rail **27** and the current integrator input **21** of the control unit **20**. The current integrator input **21** acts as a virtual earth having a voltage V_n . Having the resistive force sensitive element **30** and the control unit **20** both connected to the same voltage supply rail **27** allows the circuitry within the control unit **20**, which measures the integrated current value, to be referenced to the voltage supply rail. This configuration may also allow the measurement to be made ratiometric and substantially decoupled from any changes in the supply rail voltage V_{dd} . Although the supply rail voltage V_{dd} can be a fixed voltage, there may be unintended fluctuations in the supply rail voltage V_{dd} .

A limit resistor **24** having a value R_L is connected in series with the resistive force sensitive element **30**, between the fixed voltage supply rail **27**, and the current integrator input **21**. The limit resistor may, for example, have a resistance value in the range 100Ω to soon. The limit resistor **24** R_L limits the maximum current flow through the resistive force sensitive element **30** to the current integrator input **21** if the resistance of the resistive force sensitive element **30** drops to a low value. This configuration can prevent the current from exceeding a maximum value that can be accepted and measured by the current integrator **22**. The resistance of some QTC materials can drop to a relatively low value when subjected to a large applied force.

A bias resistor **25** having a value R_B is connected between the fixed voltage supply rail **27** and the limit resistor **24** in parallel with the resistive force sensitive element **30**. In some instances, the resistance of some QTC materials can rise to a high value when not subjected to an applied force. The bias resistor **25** provides a DC current path if the resistance of the resistive force sensitive element **30** rises to a very high value. The bias resistor **25** may, for example, have a resistance value of $1\text{ M}\Omega$ or more.

In this configuration, the value of the current flow I_n into the integrator input **21** will be approximately: $I_n = (V_{dd} - V_n) / ((R_Q * R_B) / (R_Q + R_B) + R_L)$.

In this example, each of the values in this equation other than I_n and R_Q are fixed. However, the current I_n is a function of change in the force sensitive resistance R_Q . Accordingly, the resistance value R_Q of the resistive force sensitive element can be determined from the value of the accumulated charge obtained by integration of I_n over a fixed time as measured at the current integrator input **22**. The value of the applied force can in turn be determined from the resistance value R_Q of the resistive force sensitive element. The force can be calculated based on the characteristic of the QTC material using the calculated resistance. In some applications the force applied may not need to be accurately calculated; instead a simple threshold on the output of the integrator performing the force measurement may be sufficient to provide information to the host system.

The determined force can be used to cause certain events to occur in response thereto. For example, if the portable device is a mobile phone and the force applied to an area of the touch sensitive-position panel **1** exceeds a threshold value, then the mobile phone may perform a first action. For example, the menu of the mobile phone can return to a home screen. However, if the force does not exceed the threshold, then the menu may not change or a different action can occur. In addition, more than one threshold can be used to trigger various events. Some events can be triggered when a threshold is met and exceeded. Other events can be triggered when the force is below or equal to the threshold. Some events can be triggered when the threshold is exceeded. Other events can occur when the force is below the threshold. Still further actions can be performed based directly on the applied force. Examples include, but are not limited to, a zoom-in action may be applied where the level of zoom being proportional to the applied force.

With reference to FIG. 4, another circuit **33** that includes a QTC resistive force sensitive element **30** is shown and described. The resistive force sensitive element **30** is in communication with a control unit **20**. The control unit **20** is connected to a ground rail **19** and a fixed voltage supply rail **27** that has a voltage V_{dd} .

In this example, the resistive force sensitive element **30** has a resistance R_Q and is connected between a voltage driver output **26** of the control unit **20** and at an input **21** of

a current integrator **22** of the control unit **20**. The voltage driver output **26** supplies an alternating voltage varying between a high voltage and a low voltage while the current integrator input **21** acts as a virtual earth at a voltage midway between the high and low voltages. In particular, the voltage driver output **26** supplies an alternating voltage varying between a high voltage substantially equal to the supply rail voltage V_{dd} and a low voltage of substantially zero volts at ground, while the current integrator input **21** acts as a virtual earth at a voltage V_n which is approximately half of V_{dd} . Although the alternating voltage is a positive voltage relative to the ground voltage, the alternating voltage is an alternating bi-polar voltage relative to the virtual earth at the current integrator input. The voltage driver can also drive one or more drive electrodes **4(X)**.

In this example, the current integrator input **21** voltage is nominally midway between the high and low voltages of the alternating voltage. However, other values of the current integrator input voltage between the high and low voltages could be used. The value of the current: integrator input voltage will depend on how the alternating voltage varies with time.

In some examples, the voltage driver output **26** of the control unit **20** used to supply the alternating voltage to the resistive force sensitive element **30** may also be used to drive a drive electrode **4(X)** of the touch position sensing panel **1**. In such a configuration, the force sensor **30** may be shielded by being placed behind a conductive ground plane. Other types of shielding can also be used. Shielding can prevent capacitive coupling that can cause the force sensing element to become touch sensitive as well as force sensitive. In various applications this may be undesirable as the force sensor should respond to the force applied not to the proximity of the object applying the force.

Supplying the force sensing element **30** with an alternating voltage having values that are above and below the voltage of the current integrator input **21** can allow the circuits within the control unit **20** used to measure the integrated current value to carry out differential measurement of the current flow through the resistive force sensitive element **30**. Such differential measurement may facilitate noise cancellation for some types of noise.

A limit resistor **24** having a resistance R_L is connected between the voltage driver output **26** and the current integrator input **21**. The limit resistor **24** is connected in series with the resistive force sensitive element **30**.

A bias resistor **25** having a resistance R_B is connected between the voltage driver output **26** and the limit resistor **24**. The bias resistor **25** is connected in parallel with the resistive force sensitive element **30**.

The resistance value R_Q of the resistive force sensitive element can be determined from current values measured by differential current measurement at the input **21** of the current integrator **20**. The value of the applied force can in turn be determined from the resistance value R_Q of the resistive force sensitive element. The force can be determined based on the characteristics of the QTC material using the calculated resistance.

With reference to FIG. 5, another example of a circuit **34**, is shown and described. The circuit **34** includes three QTC resistive force sensitive elements **30 a**, **30 b**, and **30 c** in communication with the control unit **20**. Also, the control unit **20** is connected to a ground rail **22** and a fixed voltage supply rail **27** that has a voltage V_{dd} .

In this example, each of the resistive force sensitive elements **30a**, **30b**, **30c** is connected to a respective voltage driver output **26a**, **26b**, **26c** of the control unit **20**. All of the

resistive force sensitive elements **30a**, **30b**, **30c**, also are connected to an input **21** of a current integrator **22** of the control unit **20**. Each voltage driver output **26a**, **26b**, **26c** periodically supplies an alternating voltage varying between a high voltage and a low voltage. The current integrator input **21** acts as a virtual earth at a voltage midway between the high and low voltages. In particular, each voltage driver output **26a**, **26b**, **26c** supplies an alternating voltage varying between a high voltage equal to the supply rail voltage V_{dd} and a low voltage of zero volts at ground. In addition, the current integrator input **21** acts as a virtual earth at a voltage V_n which is half of V_{dd} . In some examples, each voltage driver output **26a**, **26b**, **26c** of the control unit **20** used to supply the alternating voltage to a resistive force sensitive element **30a**, **30b**, **30c** may also be used to drive a drive electrode of the touch position sensing panel.

The timing of the periodic operation of the three voltage driver outputs **26a**, **26b**, **26c** may be synchronized so that one of the three voltage driver outputs **26a**, **26b**, **26c** is emitting an alternating voltage at any time. Accordingly, a single current integrator input **21** can measure the current flow through each of the resistive force sensitive elements **30a**, **30b**, **30c** in turn.

A respective limit resistor **24a**, **24b**, **24c**, is connected between each voltage driver output **26a**, **26b**, **26c** and the current integrator input **21** in series with a respective resistive force sensitive element **30a**, **30b**, **30c**.

A respective bias resistor **25a**, **25b**, **25c** is connected between each voltage driver output **26a**, **26b**, **26c** and a respective limit resistor **24a**, **24b**, **24c** in parallel with a resistive force sensitive element **30a**, **30b**, **30c**.

The resistance value of each resistive force sensitive element **30a**, **30b**, **30c** can be determined from the respective current values determined by differential current measurement at the current integrator input **21** during the respective driver intervals. For each force sensing element **30a**, **30b**, **30c**, the value of the applied force can in turn be determined from the determined resistance value of the respective resistive force sensitive element. The force can be determined based on the characteristics of the QTC material using the calculated resistance.

In this example, the resistance values of three resistive force sensitive elements **30a**, **30b**, **30c**, are measured using a single current integrator input **21**. Other numbers of current integrators **22** can also be used.

As shown, the resistance values of multiple resistive force sensitive elements **30a**, **30b**, **30c** are measured using multiple voltage driver outputs **26a**, **26b**, **26c** and a single current integrator input **21**. In other examples, a single voltage driver output **26** and multiple current integrator inputs **21** could be used. In yet other examples, multiple voltage driver outputs **26** and multiple current integrator inputs **21** could be used. For example, N voltage driver outputs **26** and M current integrator inputs **21** could be arranged to measure N×M resistive force sensitive elements **30**.

In the previous examples, limit resistors **26** are shown. However, limit resistors **26** may not be included if the characteristics of the resistive force sensitive element **30** are such that the resistance of the resistive force sensitive element is sufficiently high that the maximum current flow through the resistive force sensitive element is acceptable to the current integrator **22**. Further, limit resistors **26** may not be used in the illustrated circuits if the current integrators **22** include an integral limit resistor.

In the illustrated examples, bias resistors **25** are used. However, bias resistors **25** may not be included if the

characteristics of the resistive force sensitive element **30** are such that the resistance of the resistive force sensitive element **30** is sufficiently low that a DC current path through the resistive force sensitive element exists.

In the illustrated examples, force sensitive resistance elements **30** provide a force sensor. However, other types of resistive elements can also be used to provide additional sensing functionality. For example, light dependent resistance elements, infra red dependent resistance elements, or temperature dependent resistance elements can also be used. Each of these types of elements provides one or more additional sensing features in addition the position sensing provided by the drive electrodes **4(X)** and sense electrodes **5(Y)**.

In the illustrated example, the drive electrodes **4(X)** and the sense electrodes **5(Y)** may be formed as two separate layers. However, other arrangements are possible. The mutual capacitance touch position sensor can alternatively be formed as a single layer device having co-planar drive electrodes and sense electrodes both formed on the same surface of a single substrate.

In the illustrated examples, the drive electrodes **4(X)** and sense electrodes **5(X)** may be rectangular strips. However, other arrangements are possible. The shape of the drive and sense electrodes and the interconnection between the channels of any given electrode may be modified according to the type of touch with which the position sensing panel is intended to be used. For example, the stripes may have saw-tooth or diamond shaped edges with attendant, inter-stripe gaps to facilitate field interpolation to aid in smoothing positional response.

The number of drive electrodes and sense electrodes shown is by way of illustration only, and the number shown is not limiting.

While the above discussion used mutual capacitance drive approaches for the discussions of examples of the sensors that may incorporate force sensors, self-capacitance drive adapted to include force sensing by application of the technologies discussed in the examples above.

Various modifications may be made to the examples described in the foregoing, and any related teachings may be applied in numerous applications, only some of which have been described herein. It is intended by the following claims to claim any and all applications, modifications and variations that fall within the true scope of the present teachings.

What is claimed is:

1. A mobile electronic device comprising:
 - a housing;
 - a capacitive touch sensing panel comprising:
 - a substrate having a first surface;
 - a plurality of drive electrodes or sense electrodes of a touch sensor disposed on the first surface;
 - a plurality of drive electrodes or sense electrodes of the touch sensor disposed on a second surface, wherein if a plurality of drive electrodes is disposed on the first surface, a plurality of sense electrodes is disposed on the second surface, wherein if a plurality of sense electrodes is disposed on the first surface, a plurality of drive electrodes is disposed on the second surface, and wherein the plurality of drive electrodes is comprised of a clear conductive material;
 - a display;
 - a cover sheet, wherein the first surface of the substrate is configured to face towards the cover sheet; and

9

- an optically clear adhesive layer (OCA) disposed between the first surface of the substrate and the cover sheet;
- one or more processors comprising a voltage driver and an integrator circuit, the voltage driver configured to provide an alternating voltage;
- a first variable resistance electrode coupled to an output of the voltage driver and an input of the integrator circuit, wherein the integrator circuit is configured to measure a parameter of the first variable resistance electrode, wherein the first variable resistance electrode is configured to be driven by the alternating voltage provided by the voltage driver, and wherein the first variable resistance electrode is disposed between the capacitive touch sensing panel and the housing;
- the one or more processors configured to determine, based on the measured parameter, an amount of force applied to a sensing area of the capacitive touch sensing panel; and
- the one or more processors further configured to determine whether the amount of force exceeds a first threshold value, and if the amount of force exceeds the first threshold value, cause the mobile electronic device to trigger a first event.
2. The mobile electronic device of claim 1, wherein: the substrate further comprises the second surface; the first surface is opposite the second surface; and the second surface of the substrate is configured to face towards the display.
3. The mobile electronic device of claim 1, wherein the parameter of the first variable resistance electrode is measured over a period of time.
4. The mobile electronic device of claim 1, wherein: the clear conductive material is selected from the group consisting of indium-tin-oxide (ITO), antimony-tin-oxide (ATO), tin oxide, and a conductive polymer; the substrate is comprised of at least one of glass, polyethylene terephthalate (PET), polyethylene naphthalate (PN), or polycarbonate (PC); and the cover sheet is comprised of at least one of glass, polycarbonate, or polymethylmethacrylate (PMMA).
5. The mobile electronic device of claim 4, wherein the display is an organic light-emitting diode (OLED) display.
6. The mobile electronic device of claim 5, wherein the one or more processors is further configured to determine whether the determined amount of force exceeds a second threshold value, and if the amount of force exceeds the second threshold value, cause the mobile electronic device to trigger a second event that is different from the first event.
7. The mobile electronic device of claim 6, wherein the one or more processors is further configured to determine whether the determined amount of force exceeds a third threshold value, and if the amount of force exceeds the third threshold value, cause the mobile electronic device to trigger a third event that is different from the first event and different from the second event.
8. The mobile electronic device of claim 1, wherein the first event is selected from the group consisting of returning to a home screen and zooming in on a particular region of the display.
9. The mobile electronic device of claim 1, wherein the measured parameter is current flowing through the first variable resistance electrode.

10

10. A mobile electronic device comprising: a housing; a capacitive touch sensing panel comprising: a cover sheet; optically clear adhesive (OCA); a plurality of sense electrodes of a touch sensor, wherein the plurality of sense electrodes is comprised of conductive metal mesh; and a display;
- one or more processors comprising a voltage driver and an integrator circuit, the voltage driver configured to provide an alternating voltage;
- a first variable resistance electrode coupled to an output of the voltage driver and an input of the integrator circuit, wherein the integrator circuit is configured to measure a parameter of the first variable resistance electrode, and wherein the first variable resistance electrode is configured to be driven by the alternating voltage provided by the voltage driver; and
- the one or more processors configured to determine, based on the measured parameter, an amount of force applied to a sensing area of the capacitive touch sensing panel, determine whether that amount of force exceeds a first threshold value, and if the amount of force exceeds the first threshold value, cause the mobile electronic device to trigger a first event.
11. The mobile electronic device of claim 10, wherein the conductive metal mesh is comprised of copper or silver.
12. The mobile electronic device of claim 11, wherein the one or more processors is further configured to determine whether the determined amount of force exceeds a second threshold value, and if the amount of force exceeds the second threshold value, cause the mobile electronic device to trigger a second event different from the first event.
13. The mobile electronic device of claim 10, wherein the display is an organic light-emitting diode (OLED) display.
14. The mobile electronic device of claim 13, wherein the first event is selected from the group consisting of returning to a home screen and zooming in on a particular region of the display.
15. The mobile electronic device of claim 14, wherein the measured parameter is current flowing through the first variable resistance electrode.
16. A mobile electronic device comprising: a housing; a capacitive touch sensing panel comprising: a cover sheet; optically clear adhesive (OCA); a plurality of drive electrodes of a touch sensor and a plurality of sense electrodes of a touch sensor, wherein the plurality of drive electrodes and the plurality of sense electrodes are comprised of conductive metal mesh; and a display;
- one or more processors comprising a voltage driver and an integrator circuit, the voltage driver configured to provide an alternating voltage;
- a first variable resistance electrode coupled to an output of the voltage driver and an input of the integrator circuit, wherein the integrator circuit is configured to measure a parameter of the first variable resistance electrode, wherein the first variable resistance electrode is configured to be driven by the alternating voltage provided by the voltage driver, and

wherein the first variable resistance electrode is disposed between the capacitive touch sensing panel and the housing; and

the one or more processors configured to determine, based on the measured parameter, an amount of force applied to a sensing area of the capacitive touch sensing panel, determine whether that amount of force exceeds a first threshold value, and if the amount of force exceeds the first threshold value, cause the mobile electronic device to trigger a first event.

17. The mobile electronic device of claim **16**, wherein the conductive metal mesh is comprised of copper or silver.

18. The mobile electronic device of claim **17**, wherein the one or more processors is further configured to determine whether that amount of force exceeds a second threshold value, and if the amount of force exceeds the second threshold value, cause the mobile electronic device to trigger a second event that is different from the first event.

19. The mobile electronic device of claim **18**, wherein the measured parameter is current flowing through the first variable resistance electrode.

20. The mobile electronic device of claim **16**, wherein the display is an organic light-emitting diode (OLED) display.

21. The mobile electronic device of claim **20**, wherein the first event is selected from the group consisting of returning to a home screen and zooming in on a particular region of the display.
