(57) **ABSTRACT**

A transceiver card for a telecommunications box for trans-  
mitting data over a first optical fiber and receiving data over a  
second optical fiber. The card has transmitter for transmitting  
data over the first optical fiber, the transmitter having a laser  
and a modulator, a fiber output optically connected to the laser  
for connecting the first optical fiber to the card, a fiber input  
for connecting the second optical fiber to the card, a receiver  
optically connected to the fiber input for receiving data from  
the second optical fiber, and an OTDR optically connected  
between the transmitter and the fiber output or between the  
receiver and the fiber input. An energy level detector is also  
provided between the receiver and the fiber input.

## FIBER OPTIC TELECOMMUNICATIONS CARD WITH ENERGY LEVEL MONITORING

### CROSS REFERENCE TO RELATED APPLICATION

The present patent application is a continuation of U.S. patent application Ser. No. 12/590,185, filed Nov. 4, 2009; which is a continuation of U.S. patent application Ser. No. 10/188,643 (now U.S. Pat. No. 7,620,327), filed Jul. 3, 2002, which claims priority to U.S. Provisional Patent Application Ser. No. 60/303,932, filed Jul 9, 2001; the entirety of which are all hereby incorporated by reference.

### BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

The present invention relates generally to telecommunications and more particularly to transmitters and receivers for fiber optic networks.

#### 2. Background Information

In current fiber optic networks, an electronic data stream is fed to an optical fiber multiplexor, which is also called "a box" in the industry. Each multiplexor runs on a specific transmission standard, for example, SONET. A laser and an amplitude modulation circuit for the laser typically are located on a card, which fits into the box. The laser amplitude modulator typically pulses or alters the laser output to create an amplitude-modulated optical signal representative of the electronic data stream. The laser amplitude modulator and laser thus define a transmitter for transmitting the optical signal over an optical fiber. A receiver for the amplitude-modulated optical signals of the optical data typically includes a photodiode to convert the optical signals back into the electronic data stream. Both the transmitter and the receiver typically are located on the backplane of a single card, which is replaceable should a component fail.

The card typically also contains a connector for receiving at least one optical fiber, for example a duplex SC connector. The connectors normally are located on a faceplate of the card, the faceplate being perpendicular to the backplane.

The reading of the amplitude-modulated optical data signals using the photodiode on the card is straightforward: the optical signals either produce an electric output at the photodiode or they do not. As a result, an output electronic data stream of zeros and ones is generated.

The electronics for the amplitude modulation of the laser and for the receiving of the optical data on the card thus is relatively simple. All that is required is a pulsing circuit for pulsing the laser as a direct function of the input data and a photodiode for the receiver.

Existing amplitude modulated systems have the disadvantage that the fiber can be easily tapped and are not secure.

U.S. Pat. No. 5,455,698 purports to disclose a secure fiber optic communications system based on the principles of a Sagnac interferometer. A data transmitter is a phase modulator for modulating counter-propagating light beams sent by a receiver round a loop. The receiver includes a light source, a beamsplitter for splitting light from the light source into counter-propagating light beams and for receiving the phase-modulated light beams, and an output detector. U.S. Pat. No. 5,223,967 describes a similar Sagnac-interferometer-based system operating over a single optical fiber.

The Sagnac-interferometer-based systems described in these patents have the disadvantage that they require the light to travel over a loop, whether back and forth in a single fiber or over a long length looped fiber. As a result, either the link

budget for the single fiber must be doubled, reducing the data carrying capacity for a single fiber, or else a looped fiber with significant and expensive extra length of at least twice that of a single fiber must be laid between the transmitter and the receiver. Moreover, the receiver contains the light source, as opposed to the current installed base where the transmitter has the light source.

The Sagnac-interferometer-based systems thus are expensive to build and operate, and do not work particularly well with existing multiplexors or card formats.

Several companies currently provide OTDR (optical time-domain reflectometers) which can monitor an optical fiber and determine if the presence of and location of a break in the fiber. Such companies include Youth Communication Co. with the MW Series Mini-OTDR and OTDR modules from Tekronix Communications.

These detectors however are expensive and must be applied to the fiber away from the box.

U.S. Pat. No. 5,777,727 discloses details of OTDR technology and is hereby incorporated by reference herein.

### SUMMARY OF THE PRESENT INVENTION

An object of the present invention is to provide a transceiver card for providing secure optical data transmission over optical fiber. Another alternate or additional object of the present invention is to provide for replacement of existing cards with a transceiver card permitting ODTR and tapping detection capabilities.

The present invention provides a transceiver card for transmitting data over a first optical fiber and receiving data over a second optical fiber, the card having a transmitter for transmitting data over the first optical fiber and a receiver for receiving data from the second optical fiber, and an OTDR connected optically to the second optical fiber upstream from the receiver. Preferably, the OTDR operates at a wavelength that is different than the wavelength used for data transmission and is connected in the optical circuit via a wavelength division multiplexed coupler. By operating the OTDR at a wavelength different than the wavelength used for data transmission, the OTDR may be allowed to continuously operate without disruption of the data traffic.

Preferably, an energy level detector is also provided on the card. The energy level detector is preferably optically connected to the second fiber between the OTDR and the receiver.

The OTDR preferably is monitored by an embedded processor within the box. The processor analyzes the OTDR output data to determine if the characteristics of the optical fiber system have changed relative to a reference characteristic. If the optical fiber system has changed relative to the reference OTDR characteristic, then a degradation of the optical fiber system, which may indicate a fiber breach or a fiber tap, can be logged along the position of the degradation source relative to the location of the OTDR. The indication of degradation of the fiber system may provide an alarm signal, for example an electronic signal sent to a network operations center to indicate the measured degradation of the fiber system along with the approximate location of the degradation point, a light on the outside of the box or a sound-emitting alarm. Alternatively, the OTDR output may be connected to a display model via an electrical connection on the card for display to a human operator, or transferred by the transceiver to be analyzed at the network operations center.

The transceiver card of the present invention preferably has fiber span length ranges for operation that are compatible with standard optical multiplexor operation, for example, two to twenty kilometers or ten to one hundred kilometers. The

OTDR and energy level detector must have a measurement dynamic range that ensures proper operation over the span length limits of the transceiver card. By specifying fiber span length ranges for the OTDR and energy detector enhanced transceiver, the cost of implementation of the OTDR and energy level detector can be optimized with span length thus providing an optimized cost of implementation benefit to the customer.

The present invention thus permits a card-based transmission system incorporating an energy level detector for optical tap detection, which can provide for more secure data transmission than existing amplitude-based cards along with breach localization services from the OTDR. Because of advances in semiconductor and optical component packaging, the OTDR and energy level detector parts along with the optical transmitter and receiver components can fit all on one card compatible with most existing box dimensions.

The transmitter light source preferably is a laser, for example a semiconductor laser operating at a 1550 nm, or other, wavelength.

Preferably, the energy level detector provided on the card for measuring light energy in a fiber is connected electronically to an alarm, so that when a drop or increase in the energy level is detected, which may indicate a tap, the card may provide an alarm signal, for example an electronic signal sent to a network operations center to indicate a drop or increase in the optical energy level, a light on the outside of the box or a sound-emitting alarm. Depending upon the optical transmission method implemented, a successful tap may be placed by adding light to the system through the tapping device. Implementations of the single fiber Sagnac transmission method described in U.S. Pat. No. 5,223,967 may be susceptible to such a tapping method unless an energy level detector that monitors for an increase or decrease in the optical signal level is included as part of the design.

The card includes an optical fiber interface for at least one fiber, and preferably for two fibers. The interface may be a duplex SC connector, for example.

The card preferably is a replacement part for an existing optical multiplexor transceiver card.

The present invention also provides a method for providing a continually-operating or, preferably, a commanded operation OTDR within an existing box including the steps of:

- removing an existing transceiver card; and
- replacing the transceiver card with the card of the present invention.

The present invention also provides a method for manufacturing an optical transceiver card for transmitting data over at least one data transmitting optical fiber, the card having a transmitter and a receiver, the method comprising the steps of:

- placing a transmitter on a printed circuit board,
- placing a receiver on a printed circuit board; and
- placing an OTDR on the printed circuit board.

Preferably, an energy level detector is also placed on the printed circuit board, and a light is connected to a faceplate connected to the printed circuit board, the light indicated a change in energy at the detector or degradation of the optical fiber system.

#### BRIEF DESCRIPTION OF THE DRAWINGS

A preferred embodiment of the present invention is described below by reference to the following drawings, in which:

FIG. 1 shows schematically a card of the present invention located in an existing telecommunications box, such as a multiplexor; and

FIG. 2 shows a block diagram of the transceiver of the present invention.

FIG. 3 shows a description of an analog energy level detector of the present invention.

#### DETAILED DESCRIPTION

FIG. 1 shows an existing telecommunications box 2, for example a multiplexor, refitted with a card 1 of the present invention. Box 2 has an electronic data input 3 and output 4, which connect to a motherboard 5 of the box 2. Motherboard 5 includes a bus 6 for connecting existing amplitude-based cards to the motherboard 5, and connects the input 3 and output 4, through for example, data conversion circuitry, to the bus 6. The type of bus 6 is dependent upon the box manufacturer, and different types of boxes, motherboards and buses are well known in the art. Card 1 of the present invention includes electrical connections 8 to fit into bus 6.

Card 1 also includes a faceplate 9 and a backplane 7, which preferably is a printed circuit board. Faceplate 9 may be perpendicular to backplane 7 and be flush with a front side of box 2.

Faceplate 9 may have a fiber connector 109, such as a duplex SC connector, for connecting to an output fiber 110 and an input fiber 111. Alternately, a single fiber for inputting and outputting signals could be provided.

FIG. 2 shows the card 1 of the present invention in more detail. A transmitter 10 transmits signals over optical fiber 110. Transmitter 10 includes a single laser 12, for example a semiconductor laser emitting a narrow band of light at approximately 1550 nm, or at other wavelengths. Light emitted from laser 12 passes through a modulator 16, for example an amplitude or phase modulator, directly next to or part of the same package as laser 12. The light may be depolarized by a depolarizer 14. An electronic controller 18, preferably manufactured directed on the printed circuit board of backplane 7 (FIG. 1), controls modulator 16 and may provide power to laser 12. Input data 19 is fed to the controller 18, which then controls modulator 16 to modulate the light from laser 12 as a function of the input data 19.

The transceiver of the present invention preferably operates in a phase-modulated mode, though conventional amplitude-modulated transmitters and receivers, including those using return-to-zero type signals, for example, may also be used. The phase-modulated signals have the advantage that breach detection by the energy level detector work more effectively, since the amplitude of the optical signal is constant and thus a drop in the optical signal level is more easily detected.

Optical signals are received at connector 109 from fiber 111.

Receiver 11 includes two coupler/splitters 31 and 131, each functioning as a splitter. Splitter 131 is preferably a wavelength division multiplexed coupler/splitter to allow the OTDR 132 to operate at one optical wavelength, for example 1670 nm, while the transmitted data stream 19 and received data stream 34 are carried on a different wavelength, for example 1550 nm. This functionality allows the OTDR 132 on transceiver card 1 to be commanded to continuously operate without interruption or corruption of the received data stream 34. Splitter 131 splits off the wavelength of light applicable to the OTDR into fiber 133, which has an input to OTDR 132. Splitter 31 then splits off a portion of the remaining other light, directing part of the optical energy to an

5

energy level or tap detector **33** and passes the residual light to an optical receiver **32**. Optical receiver **32** converts the optical signal from optical to electronic form to recover the electronic data stream **34** as appropriate for the optical modulation technique employed.

OTDR **132** has a control circuit **134** and a bus **135** which allows the device to be controlled by a processor. The OTDR thus can monitor the fiber **111** and provide information through bus **135** to a processor for determining the location of a breach or tap.

Detector **33** monitors the light energy in the fiber **111** via the light energy coupled to the detector by splitter **31**. If the amplitude drops during monitoring, which may indicate a tap, the detector **33** provides an alert and can, for example, send an electronic signal to the processor via bus **135** to indicate a drop or increase in the optical energy level, sound an alarm or alert network maintenance personnel, for example through an LED **133** or by sending an alarm message using transmitter **10**. Another LED **134** can provide an indication of proper signal reception. An energy level detector control circuit **233** controls the alarm threshold and energy detection and provides output indications from the energy detection circuit to a processor via bus **135** which may be shared with the OTDR control circuit **134**.

FIG. **3** shows the energy level detector **33** of the present invention in more detail. The energy level detector **33** described by FIG. **3** represents a preferred analog implementation, with other implementation circuits possible, for bounding the optical energy within an acceptable range with thresholds which may be programmable.

A photodetector or other optical to electrical conversion device **153** measures the optical signal coupled to its input by coupler/splitter **31**. The output of photodetector **153** is an electrical voltage whose level correlates to the optical power at the input to the photodetector **153** based upon the photodetector **153** transfer optical to electrical conversion transfer function. Depending upon the electrical bandwidth of photodetector **153** and the optical signal format present at the input to photodetector **153**, the electrical signal may be filtered by a low pass filter **154** to provide an average voltage level which represents the average optical power measured by photodetector **153**. After filtering the signal, the electrical signal may be conditioned and scaled by either a logarithmic or linear amplifier **155**. Scaling the data may be necessary to ensure that energy level detection can be made without performance degradation over the span length range required for the circuit. The choice of scaling type is chosen primarily based upon the optical to electrical conversion transfer function of the photodetector and the range of expected optical power levels at the photodetector **153** input based upon span length ranges. Generally, the transfer function of semiconductor photodetection devices is exponential with respect to optical to electrical conversion. For such components, the cascade of an exponential photodetector with a logarithmic amplifier offers the advantage of providing a net linear transfer function from optical power at the input to the photodetector to voltage at the logarithmic amplifier. Thus, a digitally programmable detection threshold can be developed which offers the same resolution per bit regardless of the span length of the device.

The electrical signal, after being scaled by the linear or logarithmic amplifier **155**, is compared to reference voltages by one or more comparators. As shown in FIG. **3**, comparator **156** will transition from a low to high output when the voltage output from the logarithmic or linear amplifier **155** exceeds the reference voltage established by the digital to analog (D to A) converter **158**. Conversely, comparator **157** will transition from a low to high output when the voltage output from the

6

logarithmic or linear amplifier **155** falls below the reference voltage established by the digital to analog converter **159**. The output of OR gate **160** will transition from low to high when either the output of comparator **156** or comparator **157** transitions from low to high. For the example of FIG. **3**, an alarm state is said to exist when the output of OR gate **160** is high. To indicate an alarm state, the OR gate output may trigger an audible alarm via a siren **162**, a visual alarm via a light or light emitting diode (LED) **161** or may indicate an alarm state to the processor via the energy level detector interface **233** and processor bus **135**. The reference voltages established by D to A converters **158** and **159** may be programmable through a digital processor or state machine via a digital bus **135** and an energy level detector interface circuit **233**. One or more thresholds **163** and **164** may be established to provide reference levels for comparison to determine one or more alarm states. Thus, the circuit of FIG. **3** may be configured to monitor in real time the optical power at the receiver **11** for excess light or too little light to indicate a potential optical tap, tamper or other degradation of the optical signal.

A digital circuit equivalent to FIG. **3** may be developed. Analog to digital conversion of the logarithmic or linear amplifier **155** output followed by comparison of the digital result to digital thresholds either via software or digital hardware would indicate optical energy levels within limits or not. Additional filtering via averaging of digital conversions via a moving average or other digital filtering technique could replace or supplement filtering provided by analog filter **154**. A digital implementation also offers information regarding an estimate of the measured optical signal power, both peak and average, by monitoring the analog to digital output via a computer interface.

The component sizes and types will depend upon the type of transmission desired. For example OC-3 cards may vary in size and certain component types from OC-192 cards.

While the cards may be placed in new boxes, the present invention also permits for the removal of existing optical transmission cards to be easily replaced by the enhanced security cards. The fibers are disconnected, the box **2** is simply opened and the amplitude-modulated-based card is removed. The card **1** is inserted into the bus **6** and the fibers are connected.

The card **1** of the present invention may thus provide existing boxes with continual breach localization and detection secure transmission mode capability.

Moreover, a separate OTDR which is space-consuming need not be provided.

While the energy level detector must be at the receiver side, the OTDR also could be located on the transmitter side.

What is claimed is:

1. A telecommunications monitoring method, comprising:
  - receiving an incoming optical signal at a downstream termination point, located within an optical multiplexor box, of an optical fiber;
  - splitting, within the optical multiplexor box, the incoming optical signal into a data optical signal and a test optical signal;
  - tapping the data optical signal to produce a tapped optical signal;
  - processing, within the optical multiplexor box, the data optical signal to produce a data electrical signal indicative of data encoded in the incoming optical signal;
  - processing the tapped optical signal to produce an electrical signal indicative of a power of the data optical signal;
  - and
  - performing, by an optical time-domain reflectometer (OTDR) module within the optical multiplexor box,

7

OTDR monitoring of an optical fiber selected from: an incoming optical fiber associated with the incoming optical signal and an outgoing optical fiber associated with an outgoing optical signal.

2. The method as recited in claim 1 further comprising: filtering the electrical signal indicative of the power with a low pass filter to produce an average power signal; and amplifying the average power signal to produce an amplified power signal.

3. The method as recited in claim 2, wherein processing the tapped optical signal includes providing the tapped optical signal to a photodetector and amplifying an output of the photodetector.

4. The method as recited in claim 3, wherein an optical to electrical transfer function of the photodetector is exponential and wherein amplifying the output of the photodetector comprises providing the output of the photodetector to an input of a logarithmic amplifier.

5. A telecommunications monitoring method, comprising: receiving, by an optical multiplexor box, an incoming optical signal at a downstream termination of a downstream optical fiber; splitting the incoming optical signal into a data optical signal and a test optical signal; tapping the data optical signal to produce a tapped optical signal; processing the data optical signal to produce a data electrical signal indicative of data encoded in the incoming optical signal; processing the tapped optical signal to produce an electrical signal indicative of a power of the data optical signal; performing optical time-domain reflectometer (OTDR) monitoring of the test optical signal; filtering the electrical signal indicative of the power with a low pass filter to produce an average power signal; amplifying the average power signal to produce an amplified power signal; comparing the amplified power signal to a threshold; and generating an alarm in accordance with a result of said comparing.

6. The method as recited in claim 5, wherein comparing the amplified power signal comprises comparing the amplified power signal to a plurality of thresholds and wherein generating the alarm comprises generating the alarm in accordance with a corresponding plurality of results.

7. The method as recited in claim 5, wherein the threshold comprises a reference voltage and wherein the reference voltage is programmable through a digital processor.

8. The method as recited in claim 1, wherein the incoming optical signal comprises a wavelength multiplexed signal including a first signal having a first wavelength multiplexed with a second signal having a second wavelength and wherein splitting the incoming optical signal comprises de-multiplexing the first signal and the second signal, wherein the first signal comprises the optical data signal and the second signal comprises the test optical signal.

9. A telecommunications signal processing method, comprising:

receiving, by an optical line card, a phase modulated optical signal at a downstream termination point of an optical fiber, wherein the optical signal includes a data optical signal of a first wavelength multiplexed with a test optical signal of a second wavelength; de-multiplexing the data optical signal and the test optical signal; detecting data encoded in the data optical signal;

8

performing, by the optical line card, optical time-domain reflectometer (OTDR) monitoring of the test optical signal.

10. The telecommunications signal processing method of claim 9, further comprising:

monitoring the data optical signal against a threshold to generate a signal indicative of a change in data optical signal power satisfying at least one threshold criterion; and

monitoring the data optical signal against a plurality of thresholds and generating a signal indicative of a change in data optical signal power satisfying at least one threshold criterion in accordance with a plurality of comparisons corresponding to the plurality of thresholds.

11. An optical transceiver line card for terminating an optical fiber, the optical transceiver line card comprising:

a printed circuit board to which a plurality of components are affixed, the plurality of components comprising:

a fiber connector configured to receive a downstream termination point of the optical fiber;

a wavelength-multiplexed splitter configured to: receive a phase-modulated incoming optical signal via the optical fiber; and

split the incoming optical signal into a data optical signal and a test optical signal, wherein a wavelength of the data optical signal and a wavelength of the test optical signal differ;

an optical receiver configured to receive the data optical signal and produce an electrical signal indicative of data encoded in the incoming optical signal; and an optical time-domain reflectometer (OTDR) module configured to:

receive the test optical signal; and

perform OTDR monitoring of the test optical signal.

12. The optical transceiver line card of claim 11, wherein the plurality of components includes:

a second splitter configured to:

receive the data optical signal;

tap a signal off of the data optical signal to produce a tapped optical signal; and

pass through a residual of the data optical signal.

13. The optical transceiver line card of claim 12, wherein the plurality of components includes:

an energy level detector configured to:

receive the tapped optical signal; and

produce an electrical signal indicative of an energy of the tapped optical signal.

14. The optical transceiver line card of claim 11, wherein the plurality of components includes:

an OTDR controller configured for providing monitoring information indicative of the OTDR monitoring to a processor bus accessible to an external processor.

15. The optical transceiver line card of claim 14, wherein the plurality of components includes:

an energy level controller configured for providing energy level threshold information to the processor via the processor bus.

16. A method for monitoring optical fibers with an optical time domain reflectometer (OTDR) module integrated on a transceiver line card, the method comprising:

receiving, by the transceiver card located in an optical multiplexor box, an incoming optical signal at a downstream termination of an optical fiber;

splitting, within the optical multiplexor box, the incoming optical signal into a data optical signal and a test optical signal;

tapping the data optical signal to produce a tapped optical signal;

processing, within the optical multiplexor box, the data optical signal to produce a data electrical signal indicative of data encoded in the incoming optical signal; 5

processing the tapped optical signal to produce an electrical signal indicative of a power of the data optical signal;

receiving the test optical signal by the optical time-domain reflectometer (OTDR) module; and

monitoring, by the OTDR module, the optical fiber by 10 performing OTDR monitoring of test optical signal.

**17.** An optical fiber monitoring method, comprising:

receiving, by a transceiver line card, located in an optical multiplexor box and including an integrated optical time-domain reflectometer (OTDR), an incoming optical signal via a first optical fiber; 15

sending, by the transceiver card, an outgoing optical signal via a second optical fiber;

tapping a tapped optical signal off of the incoming optical signal; 20

processing, within the optical multiplexor box, a data optical signal split off of the incoming optical signal to produce a data electrical signal indicative of data encoded in the incoming optical signal;

processing the tapped optical signal to produce an electrical signal indicative of a power of the data optical signal; 25

and

performing, by the integrated OTDR module, OTDR monitoring of a particular optical fiber selected from the group consisting of: the first optical fiber and the second 30 optical fiber.
