(57) **ABSTRACT**

An apparatus having a microphone, an analog to digital converting circuit, a semiconductor memory an, input device, and a controller. Wherein the analog to digital converting circuit converts an output signal from the microphone into a digital signal. The semiconductor memory stores the output signal from the analog to digital converting circuit, and the input device carries out input of a record start and a record end. The controller, according to the input from the input device, carries out control to start and stop writing into the semiconductor memory a digital signal from the analog to digital converting circuit. When the input device is operated and a predetermined time interval has passed, the controller starts writing the digital signal from the analog/digital conversion circuit into the semiconductor memory.

RECORDING APPARATUS, REPRODUCING APPARATUS, AND RECORDING AND/OR REPRODUCING APPARATUS

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a recording apparatus, a reproducing apparatus, and a recording and/or reproducing apparatus, and particularly to a recording apparatus, a reproducing apparatus, and a recording and/or reproducing apparatus having a storage device.

2. Prior Art

A voice signal recording apparatus such as a portable, small-size tape recorder and an optical magnetic disc apparatus capable of writing normally has a built-in microphone for recording in a cabinet thereof. The cabinet also has operation pushbutton switches such as a recording start pushbutton switch and a stop pushbutton switch.

These pushbutton switches are usually provided with a click mechanism so that a user can feel when a pushbutton switch is depressed, which assures the operation.

The above-mentioned small-size voice signal recording apparatus has a problem that a click sound is also recorded because it is impossible to assure a sufficient distance between a microphone and, for example, a recording start pushbutton switch.

FIG. 1(A) through FIG. 1(F) show a concrete example. If a recording start pushbutton switch is depressed at time t_1 and released at time t_2 as shown in FIG. 1(A), and a stop pushbutton switch is depressed at time t_3 and released at time t_4 as shown in FIG. 1(B), then, as shown in FIG. 1(C), a voice is generated at each of these operations. The voices have the maximum amplitude at t_1 , t_2 , t_3 , and t_4 , respectively and the amplitude is gradually attenuated for a time interval T. Consequently, as shown in FIG. 1(f), the click sounds are inputted over the voice to be recorded. On the other hand, as shown in FIG. 1(E), recording starts with a delay of $\Delta 1$ after time t_1 when the recording start pushbutton switch is specified, and the recording terminates with a delay of $\Delta 2$ after time t_3 when the recording stop pushbutton switch is specified. That is, as shown in FIG. 1(F), three click voices are recorded over the voice to be recorded.

Thus, a small-size voice signal recording apparatus having a built-in microphone has a problem that if a pushbutton switch provided with a click mechanism is used for improving operation feeling for a user, the click sound of the pushbutton switch is also unnecessarily recorded.

SUMMARY OF THE INVENTION

It is therefore an object of the present invention to provide a recording apparatus which resolves the above-mentioned problem.

It is another object of the present invention to provide a reproducing apparatus which resolves the above-mentioned problem.

It is a further object of the present invention to provide a recording and/or reproducing apparatus which resolves the above-mentioned problem.

According to the present invention, there is provided a recording apparatus including a microphone, an analog to digital converting circuit, a storage device, an input device, and a controller. The analog to digital converting circuit converts an output signal from the microphone, into a digital signal. An output signal from this analog to digital convert-

ing circuit is written in the storage device. The input device is capable of entering at least a recording start and recording stop. The controller, according to the operation of the input device, controls start and stop writing into the storage device of a digital signal produced from the analog to digital converting circuit. The controller controls so as to start writing into the storage device the digital signal from the analog to digital converting circuit when a predetermined time interval has passed after the input device is operated.

According to the present invention, there is provided a reproducing apparatus including a storage device, time setter, a memory, and a controller. At least one dynamic data is written into the storage device. The time setter is used for specifying a time. The memory stores a time data specified by the time setter. The controller reads out the dynamic data from the storage device according to the time data stored in the memory.

According to the present invention, there is provided a recording and/or reproducing apparatus including a microphone, an analog to digital converting circuit, a semiconductor memory, a digital to analog converting circuit, an input device, a controller, and a cabinet. The analog to digital converting circuit converts an output signal from the microphone, into a digital signal. The semiconductor memory stores an output signal from the analog to digital converting circuit. A digital signal read from the semiconductor memory is converted into an analog signal by the digital to analog converting circuit. The input device at least enters a recording start, recording stop, and reproduction start. The controller, according to an operation of the input device, controls writing of a digital signal from the analog to digital converting circuit into the semiconductor memory and reading of a digital signal from the semiconductor memory. The cabinet is provided with the microphone, the analog to digital converting circuit, the digital to analog converting circuit, and the input device.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1(A) to (F) are to be used to explain the relationship between a click sound generated when a recording start pushbutton or a recording stop pushbutton is depressed and a result of recording.

FIG. 2 is a block diagram showing a configuration of an IC recorder as a recording and/or reproducing apparatus according to an embodiment of the present invention.

FIG. 3 is a front external view of the IC recorder according to the embodiment.

FIG. 4 is a block diagram showing a configuration of a power section of the IC recorder.

FIG. 5 is a flowchart showing a procedure of recording by the IC recorder.

FIG. 6(A) to (G) are to be used to explain the relationship between a click voice generated by the recording start pushbutton or recording stop pushbutton, and a recording procedure.

FIG. 7 is a flowchart showing a procedure of reproducing by the IC recorder.

FIG. 8 is a flowchart showing a procedure of alarm reproduction by the IC recorder.

DETAILED DESCRIPTION OF THE INVENTION

Hereinafter, a recording and/or reproducing apparatus according to the present invention will be explained in detail with reference to the attached drawings. The recording

and/or reproducing apparatus will be explained as a recording/reproducing apparatus (hereinafter, referred to as an IC recorder) in which a signal from a microphone is stored in a semiconductor memory, and a signal read from the semiconductor memory is outputted from a speaker.

As shown in FIG. 2, for example, the IC recorder 1 has:
 a recording section 10 which converts a voice signal from a microphone 11 into a voice data and stores it in a semiconductor memory 9;
 a reproducing section 20 which reads out the voice data from the semiconductor memory 9; converts it into a voice signal, and drives a speaker 24;
 a controller 30 which controls the recording section 10;
 a display section 40 which displays an operation state and an operation procedure;
 a power source 50 for supplying power to the controller 30 and others; and
 an input device 60 for a user to carry out operations.

The recording section 10, as shown in FIG. 2, has: an amplifier 12 for amplifying a voice signal from the microphone 11; a automatic gain controller 13 (hereinafter, referred to as AGC) for adjusting the voice signal amplified by the amplifier 12 to be at a proper level; an encoder 14 for converting a voice signal from the AGC 13 into voice data; and a buffer memory 15 for delaying the voice data from the encoder 14.

A voice entered to the microphone 11 is converted into a voice signal by the microphone 11 and supplied to the amplifier 12. The amplifier 12 amplifies the voice signal and supplies a resultant signal to the AGC 13. The voice signal which has been amplified by the amplifier 12 is further amplified by the AGC so as to obtain an appropriate level, which is then supplied to the encoder 14.

Because a voice signal has an intimate correlation with time the encoder 14, for example by way of adaptive differential pulse code modulation (hereinafter, referred to as ADPCM), encodes a voice signal with a small amount of data so as to generate a voice data, which is supplied to the buffer memory 15.

The buffer memory has a capacity sufficient to store the voice data from the encoder 14 for a predetermined time interval, and it temporarily stores the voice data from the encoder 14 and then supplies the data to the semiconductor memory 9.

The semiconductor memory 9 is made of an involatile memory in which contents of a storage device will be held without disappearing even if a power source of a memory, for example, electrical erasable/programmable read-only memory (hereinafter, referred to as EEPROM), is turned off. The semiconductor memory stores the voice data supplied from the buffer memory 15 as well as a control data (hereinafter, referred to as TOC data) which controls a voice data, by indicating in which area the voice data is stored. For example, the semiconductor memory 9 has a storage capacity of 16 M bytes and can store 8 minutes of voice data corresponding to a voice signal of 200 to 3400 Hz at an SP mode which will be explained later, and for 16 minutes a voice data corresponding to a voice signal of 200 to 1700 Hz at an LP mode which will be explained later.

On the other hand, the reproduction section 20, as shown in FIG. 2, includes: a decoder 21 for converting the voice data from the semiconductor memory 9, into a voice signal a filter 22; and an amplifier 23 which amplifies the voice signal from the filter 22 and supplies the signal to a speaker 24.

The decoder corresponds to the encoder 14 of the recording section 10. The voice data which has been read out of the

semiconductor memory 9, i.e., the voice data which has been encoded by the ADPCM method is decoded by this decoder so as to generate a so-called PAM signal. The filter 22 eliminates a high frequency component exceeding a voice zone from this PAM signal and outputs a voice signal. The signal from the decoder 21 is supplied to the amplifier 23, which amplifies the voice signal and drives the speaker 24. The voice which has been recorded is outputted from the speaker 24.

The controller 30, as shown in FIG. 2, includes: a ROM 31 which stores a program used for controlling operation of the IC recorder; a microcomputer (hereinafter, referred to as CPU) which executes the program stored in the ROM 31 for controlling the semiconductor memory 9 and the recording section 9; a timer 33 for time count; and a random access memory 34 (hereinafter, referred to as RAM) which temporarily stores a time, a result of program execution or the like.

The controller is supplied with signals from various pushbuttons 61a-61k arranged in the input device 60. When one of the pushbuttons 61a-61k is depressed, the CPU 32 reads out a corresponding program from the ROM 31 and executes the program for controlling a necessary section. For example, if a recording start pushbutton 61k which will be detailed later is depressed, the CPU 32 reads out a program corresponding to recording from the ROM 31 and executes the program so as to operate the amplifier 12, the AGC 13, and the encoder 14. The voice data temporarily stored in the buffer memory 15 is stored in an empty storage area of the semiconductor memory 9. The controller 30 controls writing and reading of voice data to/from the semiconductor memory 9. Up to ninety-nine cases of voice data can be written into each of two files A and B, each case being identified with an index number. According to an index number, a voice data is read out, or a voice data can also be read out when a specified time has come. This will be detailed later. The CPU 32 is connected to a quartz oscillator 35 for operating the timer 33. As will be detailed later, voice data stored in the semiconductor memory 9 is read out at a predetermined time. This is also controlled by the CPU 32. The controller 30 is connected to a display section 40, and the CPU 32 displays various information such as an operation state and operation procedure of the IC recorder 1, on the display section 40. The display section 40 includes a liquid crystal display (hereinafter, referred to as LCD) panel 41 and a back light 42 for illuminating this LCD panel. For example, when a menu/feed pushbutton 61s of the input device 60 is depressed, the CPU 32 successively displays a date and a time on the display section 40 so that the user can set the timer looking at this display.

Description will now be directed to a configuration of the input device 60 with reference to FIGS. 2 and 3. FIG. 3 shows a portable IC recorder having an external cabinet formed in the size of a user's palm. The cabinet contains a printed circuit board of the aforementioned recording section 10, the reproduction section 20 or the like. This IC recorder 1 is formed in such a manner that it can easily be held by a left hand of a user so that the user can operate this IC recorder simultaneously while writing with the right hand. The IC recorder 1 has an external cabinet 1a, where pushbuttons 61 of the input section 60 are arranged. As shown in FIG. 3, the external cabinet 1a is provided with a hand strap 1b which is used by the user when the user carries the IC recorder 1.

The input section is composed of the following pushbuttons: the menu/feed pushbutton 61a, a reproduction pushbutton 61b for starting a reproduction, a return/feed push-

button **61c** for setting an index number, a file select pushbutton **61** for switching between the aforementioned two files A and B, a stop pushbutton **61e** for terminating recording or the like, an SP/LP pushbutton **61f** for switching between an SP mode and an LP mode, a light pushbutton **61g** for turning the back light **42** on, a display pushbutton **61h**, an index pushbutton **61i** for setting an index, an erase pushbutton **61j** for erasing a voice data stored in the semiconductor memory **9**, and a recording start pushbutton **61k** for starting a recording. Among these pushbuttons, those which are used most frequently, i.e., the reproduction pushbutton **61b** and the return/feed pushbutton **61c** are arranged in the notched portion of a side surface at the upper left of the external cabinet **1a** in FIG. 3, so that the user can easily operate these pushbuttons with his/her left thumb. The recording start pushbutton **61k** which is also used frequently is formed larger than the other pushbuttons and arranged at the center of the main surface of the external cabinet **1a** so that the user can easily operate this pushbutton with his/her left thumb. When one of these pushbuttons is operated a corresponding mechanical switch located below the depressed pushbutton is operated. At this time, a click sound is generated. The click sound will be detailed later.

The aforementioned microphone **11**, the LCD panel **41** and the speaker **24** are also arranged on this main surface of the external cabinet **1a**. Because the IC recorder is formed small so as to be convenient for carrying, the microphone **11** is located near the recording start button **61k**.

The input device **60** includes: a hold lamp **62** that indicates a hold mole; a record/reproduce lamp **63** which indicates recording or reproduction is in progress; a volume switch **64** for adjusting volume of the reproduced voice; and an earphone jack (not shown). As shown in FIG. 3, The record/reproduce lamp **63** and the hold lamp **62** are arranged on the main surface of the external cabinet **1a** so that they can easily be seen while using. A hold switch (not shown), the volume switch **64**, and the earphone jack are used less frequently and arranged on the side portion of the external cabinet **1a**. When the hold switch is operated operation of the operation pushbuttons of the input device **60** is invalidated so as to prevent malfunction of the IC recorder while carrying.

Subsequently, description will be directed to the power source section **50**. For example, as shown in FIG. 4, the power source section includes: a battery **51**; a DC/DC converter **52** for increasing an output voltage of the battery **51**; a voltage detecting circuit **53** for detecting an output voltage of the battery **51**; and a capacitor **54** for charging with an output voltage of the DC/DC converter **52**.

As has been explained, the IC recorder **1** is for portable use and formed in the size of a person's palm. Consequently, the battery **51** should also be small and is composed of a single cell of SUM-4 type. The output voltage of the battery **51**, i.e., 1.5 volt is increased by the DC/DC converter **52** to a voltage required for operation of the amplifiers **12**, **23**, CPU **32** and others, and current of the resultant voltage is supplied to each of the circuits.

The voltage detecting circuit **53** detects an output voltage of the battery **51** and, when the output voltage of the battery **51** becomes, for example, 0.8 volt, terminates operation of the DC/DC converter. Electric power in the battery **51** will not be consumed after its output has reached a predetermined value, for example, 0.8 V. This prevents rapid decrease of the voltage of the battery **51** due to the DC/DC converter **52**, thus preventing liquid leaking from the battery **51**.

The capacitor **54** is connected between the ground and a power cable which connects the DC/DC converter **52** with

the timer **33** of the controller **30**, and is charged by an output of the DC/DC converter **52**. The timer **33** is operated with current supplied from this DC/DC converter **52** while the DC/DC converter **52** is operating; and with current from the capacitor **54** when the output voltage of the battery **51** is lowered or the DC/DC converter **52** is not operating when the battery **51** is taken out for replacement with a new one. That is, the capacitor **54** is a so called back-up capacitor capable of, for example, about 3 minutes of back up.

In the IC recorder **1** of such a configuration, a recording is carried out according to a procedure, for example, as shown in FIG. 5. Firstly, the user depresses the SP/LP pushbutton **61f** so as to select the LP mode or the SP mode as a recording method (step 1). The LCD panel **41** shows "SP" or "LS". Next, the user depresses the file select pushbutton **61d** so as to select file A or file B provided in the semiconductor memory **9**, and the selected file is indicated on the LCD panel **41** (step 2).

When the recording start pushbutton **61k** is depressed, a recording state starts in the IC recorder **1**. When the user speaks toward the microphone section **11**, a corresponding voice data is written in a specified area of the semiconductor memory **9** (step 3). When the stop pushbutton **61e** is depressed, the IC recorder **1** releases the recording state (step 4). When the voice data is recorded in the semiconductor memory, the following are also recorded: TOC data, file number, index number which indicates the voice signal which is being recorded. When the user wishes to record another voice data immediately after the first recording operation, the voice data is recorded in the same mode and the same file area specified first, with an index number following the first index number. That is, step 1 of mode selection and step 2 of file selection can be omitted.

As has thus far been described, the IC recorder **1** starts recording when the recording start pushbutton **61k** is depressed. Because the IC recorder **1** is of a small size and the microphone **11** is located near the recording start pushbutton **61k**, it is necessary to prevent recording of a click sound generated when the recording start pushbutton **61k** or the stop pushbutton **61e** is depressed. For this, a voice data entered from the microphone **11** is temporarily stored in the buffer memory and then supplied to the semiconductor memory **9**. This click sound is considered to be caused by changeover of a contact of a mechanical switch which is operated by the operation pushbutton arranged on the PC board of the IC recorder **1**.

For example, FIG. 6(A) shows that the recording start pushbutton **61k** is depressed at time t_{11} and released at time t_{21} , whereas FIG. 6(B) shows that the stop pushbutton **61e** is depressed at time t_{31} and released at time t_{33} . In this case, As shown in FIG. 6(C), a sound is generated having a maximum amplitude at times t_{11} , t_{21} , and t_{31} , and enduring for time T while attenuating its amplitude. Consequently, a sound to be recorded through the microphone **11** is overlapped with the click sound generated when the recording start pushbutton **61k** or the stop pushbutton **61e** is operated.

In the IC recorder according to the embodiment of the present invention, a click sound generated when the recording start pushbutton **61k** or the stop button **61e** is operated is not recorded because voice data is supplied through the buffer memory **15** to the semiconductor memory **9**. FIGS. 6(A) and (B) show that the recording start pushbutton **61k** is operated at time t_{11} i.e., the mechanical switch arranged below the pushbutton **61k** is operated initially, and the fact that the recording start pushbutton **61k** has been depressed is assured by the CPU **32** at time t_{12} . Then, read out of voice data from the buffer memory **15** is started by a control signal

from the CPU 32 at a time t_{13} when a predetermined time $\lambda 1$ has passed from time t_{12} . The voice data is written into the semiconductor memory 9 according to an address specified by the CPU 32, thus starting the recording operation. At this time, the voice data which is read out from the buffer memory 15 is a data which is read out from an address corresponding to a time after a lapse of time from t_{11} to t_{13} . The aforementioned predetermined time $\lambda 1$ is a time required for attenuation to an unbearable level of a click sound generated when an operation pushbutton such as a recording start pushbutton is depressed. As shown in FIG. 6(D), the microphone 11 outputs a signal containing a click sound generated when the recording start pushbutton 61k is depressed. However, as shown FIG. 6(E), the buffer memory 15 outputs a signal not containing a component of the click sound which can be heard by the user. Consequently, there is no problem that the signal is written into the semiconductor memory 9 as it is. Whether or not the aforementioned predetermined time $\lambda 1$ has passed is counted by a timer function provided in the CPU 32 or by using the timer 33.

As shown in FIG. 6(C), the aforementioned click sound is also generated when the user has released the recording start pushbutton 61k, i.e., when the pushbutton 61k is restored. That is, at time t_{21} , user's finger leaves the recording start pushbutton 61k, i.e., the mechanical switch arranged below the pushbutton 61k is operated by the second half; and at time t_{22} , the fact that the finger has left the recording start pushbutton 61k is confirmed by the CPU 32. Then, the recording operation is temporarily stopped at a data corresponding to time t_{21} , and is re-started at time t_{23} when the predetermined time $\lambda 1$ has passed from time t_2 . When the fact that the user's finger has left the recording start pushbutton 61k is confirmed at time t_{22} , writing into the buffer memory 15 starts with voice data from an address corresponding to time t_{21} , whereas read out starts with a voice data from an address corresponding to a moment when the predetermined time $\lambda 1$ has passed and the data is written into the semiconductor memory 9 at an address specified by the CPU 32. As a result, in the same way as the aforementioned click sound generated when the recording start pushbutton 61k is depressed, the buffer memory 15 outputs a voice data containing a component of the click sound which cannot be heard practically by the user. Thus, substantially no problem is caused. According to the present embodiment, the click sound generated by operation of the recording start pushbutton or the like has a length measured to be about 10 msec. Consequently, the aforementioned time required for reducing the noise generated by the click sound can be very short. Therefore, practically no problem is caused if the recording operation is interrupted as shown in FIG. 6(F).

The recording operation can be terminated by depressing the stop pushbutton 61e. The click sound is also generated twice when the stop pushbutton 61e is operated: as shown in FIG. 6(C), when the pushbutton 61e is depressed and when the pushbutton 61e is released. The stop pushbutton 61e is depressed at time t_{31} , i.e., the mechanical switch arranged below the pushbutton 61e is operated by the first half, and the fact that the stop pushbutton 61e has been depressed is confirmed by the CPU 32 at time t_{32} . Then, the recording operation is stopped with a data corresponding back to time t_{31} . The recording operation is terminated at a moment when a data in the buffer memory 15 at addresses corresponding to a time lapse between t_{31} and t_{32} has been written into the semiconductor memory 9.

As has been described above, the voice data written in the semiconductor memory 9 actually contains a component of the click sound as shown in FIG. 6(G), but the click sound

has been attenuated sufficiently to an unbearable level. Consequently, there is no practical problem when reproducing the voice data from the semiconductor memory 9.

It should be noted that the aforementioned predetermined time $\lambda 1$ is a time which passes while a click sound generated by operation of the recording start pushbutton 61k travels to the microphone 11. Consequently, its value is determined by a distance between the recording start button 61k and the microphone 11.

Description will now be directed reproduction of a voice data which has been recorded. The reproduction proceeds, for example, as shown in FIG. 7. Firstly, when the file select pushbutton 61d of the IC recorder 1 is depressed by a user, file "A" or "B" is selected in the semiconductor memory 9, and the one selected appears on the LCD panel 41 (step 11). Next, the user depresses the return/feed pushbutton 61c so as to select an index number recorded in the semiconductor memory 9 (step 22). When the reproduce pushbutton 61b is depressed, the IC recorder reproduces the voice data desired by the user (step 13). In order to stop the reproduction, depress the stop pushbutton 61e. To proceed to another job or return back to a preceding job, confirm that no reproduction or recording is in progress and depress the return/feed pushbutton 61c so as to select the following or the preceding index number, data of which is reproduced when the reproduce pushbutton 61b is depressed.

Moreover, the controller 30 of the IC recorder 1 is provided with a crystal oscillator 35. By using this crystal oscillator 35 and the timer 33, a date and time are displayed on the LCD panel 41. The date and time can be set as follows. When the menu/feed pushbutton 61a is depressed, a date appears on the LCD panel and a date setting mode is set in. The IV recorder 1 can set a date by pressing the return/feed pushbutton 61c. When the menu/feed pushbutton 61a is depressed in this state, the mode is switched to a time setting mode, and the time appears on the LCD panel. The IV recorder 1 can set a time by depressing the return/feed pushbutton 61c. The IC recorder 1 terminates the time setting mode when the stop pushbutton 61e is depressed.

Furthermore, the IC recorder 1 is capable of so called alarm reproduction, i.e., reading out a voice data from the semiconductor memory 9 at a predetermined time which has been set by the timer 33. This alarm reproduction can be set, for example, as shown in FIG. 7. Firstly, in step 21, a user depresses the file select pushbutton 61d and the return/feed pushbutton 61c so as to select a file and index number to be read out. The necessary data is written in the RAM 34. Then, in step 22, the IV recorder 1 sets the alarm reproduction mode when the menu/feed pushbutton 61a is depressed. "ON" or "OFF" appears on the LCD panel. One of these is selected by depressing the return/feed pushbutton 61c. When "ON" is selected and the menu/feed pushbutton is further depressed as step 3, the alarm function enters ON state. The IC recorder 1 proceeds to step 24 when the menu/feed pushbutton 61a is depressed. In step 24, the user can select a desired day of the week by pressing the return/feed pushbutton 61c. If the return/feed pushbutton 61c is further depressed after selecting the day of the week, a day data concerning this day is written into the RAM 34, and the IC recorder proceeds to step 25. In step 25, the user can select a desired time by pressing the return/feed pushbutton 61c. When the user depresses the stop pushbutton 61e, the IC recorder writes a day data concerning this day into the RAM 34, terminating the alarm reproduction mode setting. In the IC recorder 1 in which the alarm reproduction mode has been set in, when the timer 33 counts the same time as the alarm setting, the CPU 32 reads out the data

which has been written in the RAM 34, i.e., file data, index number, day data and time data to be executed. Thus, the voice data corresponding to the RAM 34 is read from the semiconductor memory 9 for reproduction.

The IC recorder 1 having the aforementioned configuration enables a user to store an aural memorandum as voice data instead of writing the memorandum on paper. The IC recorder 1, by using the buffer memory 15, makes it possible that a reproduced data is not affected by a noise due to a click sound generated by depressing operation pushbuttons at recording start and stop. The IC recorder 1 is capable of reproducing voice data at a predetermined time by setting the timer 33. For example, the IC recorder 1 can prevent the user from forgetting something which is reproduced as voice data at a necessary moment. Because the IC recorder 1 is of a small size and can be placed in a user's pocket, the user can carry it any time anywhere. Moreover, because data can be reproduced at a specified time, i.e., alarm reproduction time, the user will not miss a necessary memorandum.

The present invention thus far explained as an example of voice recording and/or reproducing apparatus having a semiconductor memory as a recording medium is not limited to this, but is also applicable to recording and/or reproducing apparatus for recording image data instead of voice data or to a voice recording/reproducing apparatus using a tape or disc as a recording medium and having a microphone built in an external cabinet. The IC recorder which employs two separate pushbutton switches for a recording start pushbutton and a stop pushbutton can also be realized as an IC recorder having a single pushbutton switch for both of the recording start and stop pushbuttons.

What is claimed is:

1. A recording apparatus comprising:
 - a microphone;
 - an analog to digital converting circuit for converting an output signal from said microphone into a digital output signal;
 - a storage device for storing said digital output signal from said analog to digital converting circuit;
 - an input device for causing a recording start operation and a recording end operation; and
 - a controller for starting and stopping a writing into said storage device of said digital output signal from said analog to digital converting circuit, said controller starting said writing of said digital output signal from said analog to digital converting circuit into said storage device upon a lapse of a predetermined time interval after said input device is operated, wherein said predetermined time interval is equal to or longer than a time interval required for attenuation to an unhearable level of a noise generated upon operation of said input device.
2. The recording apparatus as claimed in claim 1, wherein said apparatus further comprises a cabinet in which said microphone and said input device are arranged.
3. The recording apparatus as claimed in claim 1, wherein said storage device includes at least two files and said output signal from said microphone having been converted into said digital output signal by said analog to digital converting circuit is written into one of said at least two files as specified by said input device as audio data, wherein each of said at least two files can be written to by a plurality of audio data.
4. The reproducing apparatus as claimed in claim 1, further comprising
 - display means for displaying an identification identified said stored digital signal,

wherein the reproducing includes a notched portion arranged on an upper left of a surface of said cabinet having said display means mounted thereon.

5. The reproducing apparatus as claimed in claim 4, wherein input device includes a button for entering a reproducing start mode, said button is arranged in said notched portion.

6. The reproducing apparatus as claimed in claim 1, wherein said cabinet has a hand strap to be used when said user carries said reproducing apparatus.

7. A recording apparatus comprising:

a microphone;

an analog to digital converting circuit for converting an output signal from said microphone into a digital output signal;

a storage device for storing said digital output signal from said analog to digital converting circuit;

an input device for causing a recording start operation and a recording end operation;

a controller for starting and stopping a writing into said storage device of said digital output signal from said analog to digital converting circuit, said controller starting said writing of said digital output signal from analog to digital converting circuit into said storage device upon a lapse of a predetermined time interval after said input device is operated,

wherein said predetermined time interval is equal to or longer than a time interval required for attenuation to an unhearable level of a noise generated upon operation of said input device; and

a cabinet in which said microphone and said input device are arranged,

wherein said controller starts writing into said storage device when said predetermined time interval has lapsed after said input device is first-half operated, and stops writing of said digital output signal into said storage device during a lapse of the predetermined time interval after said input device is second-half operated.

8. A recording and/or reproducing apparatus comprising:

a microphone;

an analog to digital converting circuit for converting an output signal from said microphone into a digital output signal;

a semiconductor memory for storing said digital output signal from said analog to digital converting circuit;

a digital to analog converting circuit for converting a digital signal read from said semiconductor memory into an analog output signal;

an input device operable by a user of said apparatus for entering at least a recording start mode;

a controller for controlling in response to an input from said input device a writing of said digital output signal from said analog to digital converting circuit into said semiconductor memory and a reading of a stored digital signal from said semiconductor memory; and

a cabinet in which said microphone, said analog/digital converting circuit, said digital/analog converting circuit, and said input device are arranged,

wherein said semiconductor memory includes at least two files and said output signal from said microphone converted by said analog to digital converting circuit into said digital output signal is written in one of said two files as specified by said input device as audio data

11

and each of said at least two files can be written to by
a plurality of audio data,
wherein said controller includes a switch for entering a
recording start mode, and
said controller starts writing into said storage device 5
when said predetermined time interval has lapsed
after said input device is first-half operated, and

12

stops writing of said digital output signal into said
storage device during a lapse of a predetermined
time interval after said input device is second-half
operated.
