# TELECOMMUNICATIONS NETWORK AND METHOD FOR TIME-BASED NETWORK ACCESS

## CROSS REFERENCE TO RELATED APPLICATIONS

The present application is a national stage entry of PCT/EP2009/001214, filed on Feb. 19, 2009, and claims priority to European Patent Application EP 08003753.4, filed in the European Patent Office on Feb. 29, 2008, the entire contents of both of which are incorporated herein by reference.

## FIELD OF THE INVENTION

The invention relates to the field of telecommunications. In particular, the invention relates a telecommunications network and a method of permitting access to said telecommunications network.

## BACKGROUND OF THE INVENTION

The past decades have seen an ever increasing demand for data capacity of telecommunications network. Telecommunications providers have adapted their networks to provide extended GSM services, like GPRS, and 3G services and are continuing to provide further services to meet the demands of their clients.

Telecommunications providers have made attempts to influence the behaviour of their clients in order to efficiently use network resources. As an example, mobile data subscriptions nowadays are usually offered using volume based billing, possibly in combination with a volume cap, thereby forcing clients to consider the amount of data to be transmitted over a network. However, the control of the client behaviour and/or terminal data transmission and, therefore, the use of the network resources is still limited.

There is a need in the art for an improved telecommunications network and method for regulating the use of network resources.

## SUMMARY OF THE INVENTION

A telecommunications network configured for providing communication access to a plurality of terminals is proposed. Each terminal comprises a unique identifier for accessing the telecommunications network. The unique identifier is preferably associated with a subscription of the terminal, e.g. the identifier of a SIM (IMSI) that is available in the terminal. The telecommunications network comprises a register, an access request receiver and an access module. The register is configured for storing the unique identifier of at least one terminal in combination with at least one grant access time interval, or an equivalent thereof, during which access for the terminal is permitted. The access request receiver is configured for receiving the access request for accessing the telecommunications network from the terminal. The access request may contain the unique identifier or a temporary identifier. The access module is configured for denying access for the terminal if the access request is received outside the access time interval, or the equivalent thereof.

A register and a serving controlling entity for use in such a network are also proposed.

A computer-implemented method of controlling access to a telecommunications network is also proposed. The telecommunications network is configured for allowing access for a plurality of terminals, each terminal comprising a unique

identifier for accessing the telecommunications network. The telecommunications network comprises a register configured for storing the unique identifier of at least one terminal in combination with at least one grant access time interval, or an equivalent thereof. An access request is received from the terminal for access to the telecommunications network. The access request may contain the unique identifier or a temporary identifier. In a further step, the grant access time interval for the terminal is verified, using the unique identifier. Access to the telecommunications network for said terminal is denied if the access request is received outside the time interval.

A computer program and a carrier for such a computer program comprising program code portions configured for executing the method are also proposed.

A terminal for use in the system and method is also proposed.

It should be appreciated that an equivalent of the grant access time interval includes a deny access time interval identifying a time interval during which an access request for access to the telecommunications network is to be denied.

The access request may be a circuit-switched access request, a packet-switched access request or a combined request.

The steps of accessing a telecommunications network are standardized in e.g. 3 GGP TS 23.060 (Release 7). It should be appreciated that the access to the telecommunications network can be denied at various access phases. The first phase of requesting network access typically involves a network attach procedure comprising several steps. Preferably, access to the telecommunications network is denied by denying network attach of the terminal. Denying at this phase provides for optimized saving of resources.

A further network access phase involves the establishment of a PDP context. Establishment of the PDP context may be denied. Although the preceding network attach already involved the use of network resources, prohibiting the establishment of a PDP context prevents effective use of the telecommunications network and hence saves resources. It should be noted that operator determined barring (ODB) as such for access to a telecommunications network is already described in 3GGP TS 23.015, V. 7.0.0. The barring possibility allows network operators to deny access to particular destinations for certain subscribers.

By providing the option of specifying one or more time intervals during which access to the telecommunications network is allowed for a particular terminal or group of terminals, the network operator planning and control of the use of network resources is facilitated. Denying or blocking access during time intervals can prove advantageous in various situations. In particular, some machine-to-machine (M2M) applications do not require the transfer of data to be immediate. If these applications are prevented from claiming one or more network resources during e.g. peak load hours, network resources can be saved. Such subscriptions may e.g. be offered at a lower subscription rate.

M2M applications typically involve hundreds or thousands of devices that only rarely require access to a telecommunications network. An example involves the electronic reading of e.g. electricity meters at the homes of a large customer base.

The embodiments of claims 2 and 13 provide for a suitable place in the telecommunications network for making available the combinations of terminal identifier(s) and associated time interval(s).

The embodiments of claims 3 and 14 provide for a dynamic time interval (and possibly a virtual or implicit time interval) during which access to the telecommunications network is

3

allowed/prohibited. These embodiments contribute to the optimum use of network resources.

The embodiments of claims 4 and 15 provide for an improved use of network resources.

The embodiments of claims 5 and 16 provide for an improved use of network resources.

The embodiments of claims 6 and 17 provides the option to inform the terminal of the grant access time interval. Such information should only be transmitted to the terminal in question. Moreover, only allowing single authentication saves network resources and saves power for the terminals.

The embodiments of claims 7 and 18 ensure that the decision whether or not to allow access (either network attach or establishment of the PDP context) to the telecommunications network is embedded at a low level of the telecommunications network, e.g. at the SGSN, reducing network resource consumption. Other solutions, such as the implementation of grant access time rules in a RADIUS server, would require several network functions, mobility management and setting up a packet data protocol (PDP) context, and, thereby, unnecessarily consume network resources in case it would be determined that the terminal accessed the telecommunications network outside the grant access time interval.

The embodiments of claims 8 and 19 allow the transmission of information to the terminal. Such information may include information concerning the applicable grant access time interval. Possibly, the information may include control information for controlling terminal operation. The control information may e.g. control the terminal to log in during a time interval wherein the network load is expected to be low. An authentication procedure is preferably performed for this terminal.

The embodiments of claims 9 and 20 provide for higher level authentication, e.g. at a GGSN, during the grant access time interval.

Hereinafter, embodiments of the invention will be described in further detail. It should be appreciated, however, that these embodiments may not be construed as limiting the scope of protection for the present invention.

#### BRIEF DESCRIPTION OF THE DRAWINGS

In the drawings:

FIG. 1 shows a schematic illustration of a telecommunications network according to an embodiment of the present invention;

FIG. 2 shows a HLR, a SGSN and a GGSN of the telecommunications network of FIG. 1;

FIGS. 3A-3D show various time diagrams of methods for using the telecommunications system of FIG. 1; and

FIG. 4 shows a schematic illustration of a terminal for use with the telecommunications network of FIG. 1.

#### DETAILED DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a schematic illustration of a packet service telecommunications network 1 in combination with a plurality of terminals A-D that may access the telecommunications network 1 for data communication.

The telecommunications network 1 comprises a radio access network 2 containing a base transceiver station 3 and a base station controller 4. The radio access network is connected to a mobile core network containing a serving controller entity 5, a register 6 and a gateway 7 providing access to a further network 8.

The serving controller entity 5 may be a serving GPRS support node (SGSN) or another entity. The SGSN 5 controls

4

the connection between the telecommunications network 1 and the terminals A-D. It should be appreciated that the telecommunications network may contain a plurality of SGSNs, wherein each of the SGSNs is connected typically to base station controllers 3 in such a way that they can provide a packet service for terminals via several base stations 3.

The register 6 may be a home location register (HLR) or another register (such as a home subscriber server for IMS).

The gateway 7 may be a GPRS gateway support node (GGSN) to e.g. the internet. Other external networks include a corporate network or another network of the operator. The GGSN 7 is connected to the SGSN 5 via a core network.

Access for the terminals A-D to the telecommunications network 1 involves a number of access phases.

The first phase involves the phase during which a terminal A-D performs an attach to the telecommunications network 1. In this phase, various communication steps are performed, including authentication steps, as exemplified in 3GPP TS 23.060 (Release 7). The authentication steps perform a security function and involve exchange of an authentication triplet (for GPRS) or quintet (for UMTS).

In a subsequent phase, a packet data protocol (PDP) context may be established to carry traffic flows over the telecommunications network 1. A PDP context typically includes a radio access bearer provided between a terminal A and the SGSN 5 and switched packet data channels or tunnels provided between the SGSN 5 and the GGSN 7. A session between the terminal A and another party would then be carried on the established PDP context. A PDP context can carry more than one traffic flow, but all traffic flows within one particular PDP context are treated the same way as regards their transmission across the telecommunications network 1.

In operation, the terminal A may indicate after the network attach phase, in a message requesting to activate the PDP context in the network, an access point name (APN) for selection of a reference point to a certain external network 8. The SGSN 5 may send a PDP context creation request to the GGSN 7 selected e.g. according to the access point name given by the terminal A or to a default GGSN known by the SGSN 5. Subsequently, the PDP context is activated by allocating a PDP context data structure in the SGSN 5 that is used by the terminal A and the GGSN 7 serving the subscribers access point. The data structure contains an IP address of the terminal A, the IMSI of the terminal A and tunnel ID's at both the SGSN 5 and the GGSN 7. The tunnel ID is a number allocated by the GGSN 7 which identifies the data related to a particular PDP context.

Various features can be controlled by the SGSN 5 during a communication session. This control may be based on information associated with the subscription and stored in the HLR 6. The information may be retrieved from the HLR 6 to the SGSN 5 to allow control at the SGSN-level.

In particular, and with reference now to FIG. 2, the HLR 6 contains a unique identifier associated with the subscription for each terminal A-D, e.g. the IMSI stored in the SIM of the terminal A-D. Each terminal A-D has been assigned a time interval during which access to the telecommunications network 1 will be granted.

In this example, for terminals A and B, access will be granted between 0800-1100 pm. For terminal C, access will be granted between 0000-0500 am. These time intervals are typically off-peak intervals for most days of the year. Batches of terminals may be defined and assigned a particular interval of the off-peak hours. For terminal D, a variable time interval x-y is scheduled, depending on the network load experienced by or expected for the telecommunications network 1. If the

network load drops below or is expected to drop below a particular threshold, access is granted to the terminal D.

Of course, the time intervals may also relate to time slots during which access to the telecommunications network 1 is denied, i.e. access deny time intervals. Multiple time intervals may be assigned to a terminal.

In order to control the use of resources of the telecommunications network 1, the SGSN 5 contains several modules for performing the operations described below in further detail. It should be noted that one or more of these modules may be implemented as software modules running on a processor (not shown). The SGSN 5 further contains memory and storage (not shown) for performing these operations in a manner generally known to the skilled person.

The SGSN 5 comprises an access request receiver 20 configured for receiving an access request from the terminals A-D for access to the telecommunications network 1. The access request of a terminal contains the IMSI of the SIM available in this terminal.

The SGSN 5 has an access module 21 configured for denying access for a terminal to the telecommunications network 1 if the access request is received outside the grant access time interval(s) for that terminal (or within the access deny interval). The access denial may relate to the network attach or the establishment of the PDP context.

Moreover, the SGSN 5 comprises a data retrieval module 22. The data retrieval module 22 is configured for retrieving data from the HLR 6, in particular the applicable access grant time interval associated with the terminals A-D from which the access request was received. However, it should be appreciated that the SGSN 5 itself may be pre-configured with respect to particular terminals and therefore already comprise the grant access time interval(s) for these terminals. This may be particularly advantageous for stationary terminals.

The SGSN 5 also comprises a PDP context establishing module 23 and an authenticator 24.

SGSN 5 may also have a network load monitor 25 configured for monitoring the network load of the telecommunications network 1. Network load information may also be obtained from other sources, e.g. other SGSNs or the HLR of the telecommunications network 1. Network monitoring may be real time and/or be based on the expected network load using mathematical models and history data to obtain an appropriate load expectation.

The operation of the telecommunications network 1, and in particular the SGSN 5, will now be described with reference to FIGS. 3A-3D.

In FIG. 3A, the access request receiver 20 of the SGSN receives an attach request from terminal A at 0700 pm in step 30. To be able to process this attach request, the SGSN needs the IMSI of the SIM available in the terminal. The attach request may contain either this IMSI or a P-TMSI assigned to terminal A by an SGSN. The P-TMSI is used to prevent transmission of the IMSI over the radio path as much as possible for security reasons. If the P-TMSI provided by terminal A is known in the SGSN, the SGSN is able to derive the IMSI. Alternatively, for a P-TMSI provided by terminal A that is not known by the (new) SGSN, the IMSI is provided either by the old SGSN or the terminal itself on request of the new SGSN. The IMSI is used by data retrieval module 22 to retrieve the grant access time interval (0800-1100 pm) from the HLR 6 to the SGSN 5 in step 31.

The grant access time interval may be communicated from the HLR 6 to the SGSN 5 in a variety of ways.

The attach request 30 is typically followed by an authentication check, step 31. The grant access time interval may be transmitted to the SGSN 5 with the authentication triplet or quintet.

The authentication procedure of the network attach phase is typically followed by a location update procedure. First an update location request 32 is transmitted from the SGSN 5 to the HLR 6. The grant access time interval may also be transmitted to the SGSN 5 in a subsequent Insert Subscriber Data message from HLR 6 (step 33). The network attach phase is finalized with an attach accept message to the terminal A (step 34).

After finalizing the network attach phase (which may comprise further steps than mentioned in the previous paragraphs), a PDP context is established. The terminal A requests establishment of the PDP context in an activate PDP context request 35.

Irrespective of the manner of obtaining the grant access time interval, the access module of SGSN 5 determines that the access request was received outside the grant access time interval. Consequently, a PDP context is not established (indicated by the cross in step 36). The terminal A is informed of the denial in step 37.

It is noted that the authenticator 24 of SGSN 5 may or may not have authenticated terminal A in the above situation. Authentication is required if the grant access time interval is transmitted from the HLR 6 to SGSN 5 in response to the update location message 32. However, authentication should not be completed if the grant access time interval is obtained in SGSN 5 with the authentication triplet/quintet. Authentication is preferred if the denial message 37 to the terminal A contains information concerning the grant access time interval.

The SGSN 5 comprises or obtains and maintains the data of the failed access request. This may e.g. be done by storing the time interval in combination with the IMSI of terminal A or by flagging the terminal A temporarily in combination with some time indication.

Another access request at a time outside the window 0800-1100 pm (step 38), again containing or followed by the IMSI of terminal A, may then be denied directly (step 39). Authentication will not be performed again.

In FIG. 3B, the network attach of terminal A is received at 0900 pm. Steps 40-45 correspond to steps 30-35. Since the network attach request is now within the time interval allocated for access for the terminal A, access module 21 controls the PDP context establishing module 23 of the SGSN 5 to establish a PDP context with the terminal A and to establish a PDP tunnel with the GGSN 7. In particular, step 46 involves a Create PDP Context Request and step 47 a Create PDP Context Response in a manner known as such. In step 48, the terminal A is informed by a Activate PDP Context Accept message. The terminal A may now follow another authentication procedure (step 49), using e.g. a RADIUS server in the further network 8.

The network load monitoring module 25 of SGSN 5 may monitor the network load of (a part of) the telecommunications network 1 or output an expected network load. The network load may be compared with a load threshold in order to evaluate the existence of a low network load situation at a particular time or time interval.

In FIG. 3C, steps 50-53 correspond to steps 30-33 of FIG. 3A. Authentication of terminal D is performed and in step 54, the terminal D is informed of a time interval x-y during which a low network load is expected. The information includes control information to control terminal D such that it accesses the telecommunications network 1 again (step 55) in such a

low network load time interval. A PDP context can be set up immediately (steps 56-58) and access to the RADIUS server is allowed.

As mentioned above, the denial of access to the telecommunications network 1 is preferably performed during the network attach. FIG. 3D shows in step 60 a network attach message of terminal A containing an IMSI. Then an authentication procedure is performed (step 61) during which the grant access time interval is received at SGSN 5. The grant access time interval and the IMSI is stored at SGSN 5. Alternatively, the grant access time interval is obtained in the location update procedure (steps 62 and 63). The network attach is denied in step 64.

As mentioned before, SGSN 5 may itself comprise pre-configured information regarding the grant access time interval for terminal A. Alternatively, the SGSN uses authenticator 24 to authenticate terminal A and to provide terminal A with information regarding the grant access time interval in step 61.

FIG. 4 shows a schematic illustration of terminal A. The terminal A comprises a transceiver module 70 for communicating with the telecommunications network 1. The terminal A further has an access request module 71. The access request module is configured for receiving information regarding the grant access time interval from the telecommunications network 1 via the transceiver module 70 and to transmit an access request to the telecommunications network only at a time within the grant access time interval.

It should be noted that the above described telecommunications network and system are especially suitable for saving resources. There may be other approaches to influence access behaviour of terminals but these are considered to waste more resources.

As an example, a network provider may allow access to the network at all times but charge a (very) high rate for data sent outside the off-peak time. This provides no incentive for the user to tear down the connection (i.e. the PDP context) to the network. It only provides an incentive to not send data during the expensive peak hour. However, an active PDP context still consumes a lot of resources in the mobile radio and core network as well as requiring an IP address. It also requires the terminal being attached to the network, meaning all kinds of mobility management features should be in place. Furthermore, this solution requires a more complicated billing system that allows charging higher rates at certain times.

Another example would include blocking access to the terminal during peak hours as a rule in a RADIUS server. However, network resources would already be consumed before access is blocked by the RADIUS server. The terminal is already allowed to attach to the network, meaning the SGSN would have retrieved information from the HLR, and is performing mobility management functions. Also, the terminal has been allowed to establish a PDP context. If the RADIUS server would reject the request for access to the external data network, the GGSN would not accept the PDP context, and the tunnel would be taken down. Attachment to the network will however continue if no additional measures were taken.

The invention claimed is:

1. A telecommunications network configured for providing access to a plurality of terminals, each terminal associated with a unique identifier for accessing the telecommunications network, wherein the telecommunications network comprises:

a register configured to store the unique identifier of at least one terminal in combination with identification of at least one associated grant access time interval, the at

least one associated grant access time interval being a time period during which telecommunications network access for the terminal is permitted;

one or more processors;

memory storing processor instructions that, when executed by the one or more processors, cause the one or more processors to carry out operations including:

an access request operation to receive an access request from the terminal and to determine the unique identifier associated with the terminal;

an access operation to deny access for the terminal if the access request is received outside the time period, wherein the telecommunications network is further configured to monitor a network load of the telecommunications network,

wherein the telecommunications network is further configured to adapt the time period depending on the monitored network load, and

wherein machine-to-machine applications are executed, and wherein the plurality of terminals for the machine-to-machine applications are denied access to the telecommunications network during peak load time intervals, the time period being outside peak load time intervals.

2. The telecommunications network according to claim 1, wherein the telecommunications network comprises a cellular network and the register is one of a home location register and a home subscriber server of the cellular telecommunications network.

3. The telecommunications network according to claim 1, wherein the access operation functions to deny the terminal a network attach to the telecommunications network.

4. The telecommunications network according to claim 1, wherein the access operation functions to deny access prior to authenticating the terminal.

5. The telecommunications network according to claim 1, wherein the operations further include an authorization operation to authorize the terminal in response to receiving the access request, and

wherein the access operation functions to deny the terminal a network attach upon receiving a further access request from the terminal.

6. The telecommunications network according to claim 1, wherein the telecommunications network further comprises a serving controller entity, the serving controller entity configured for carrying out the access request operation and the access operation, and the serving controller entity being further configured for carrying out a data retrieval operation to retrieve the identification of the at least one associated grant access time interval from the register in response to receiving the access request,

and wherein the access operation functions deny at least one of a network attach to the telecommunications network with the terminal or an establishment of a packet data protocol context with the terminal if the access request is received outside the time period defined by the retrieved identification of the at least one associated grant access time interval.

7. The telecommunications network according to claim 1, further comprising a serving controller entity configured to transmit an access denial message to the terminal in response to the access operation denying the terminal access to the telecommunications network.

8. The telecommunications network according to claim 1, further comprising a gateway to a further network, the gateway being configured to allow further authentication of the terminal.

9. The telecommunications network according to claim 1, wherein the network load is one of (i) monitored in real-time or (ii) based on an expected network load.

10. The telecommunications network according to claim 1, wherein each of the plurality of terminals of the machine-to-machine applications has a respective time period that is determined according to one of: (i) a respective pre-defined grant-time interval, (ii) a variable time interval scheduled based on actual network load, and (iii) a variable time interval scheduled based on an expected network load,

and wherein access to the telecommunications network is granted to the terminal of the plurality of terminals if its respective time period is one of below a particular threshold, or predicted to be below the particular threshold.

11. The telecommunications network according to claim 1, wherein the plurality of terminals of the machine-to-machine applications have one or more time periods assigned to a particular one or more of the plurality.

12. The telecommunications network according to claim 1, wherein the telecommunications network further comprises a network load monitor and wherein the network load monitor obtains network load information from one of a home location register (HLR), or a Home Subscriber Server (HSS) of the telecommunications network.

13. The telecommunications network according to claim 1, wherein the telecommunications network further comprises a network load monitor and wherein the network load monitor obtains network load information from a low level of the telecommunications network.

14. The telecommunications network according to claim 1, wherein the telecommunications network further comprises a network load monitor and wherein the network load monitor obtains network load information from a SGSN of the telecommunications network.

15. A computer-implemented method of controlling access to a telecommunications network, the telecommunications network being configured for allowing access for a plurality of terminals, each terminal associated with a unique identifier for accessing the telecommunications network, the telecommunications network comprising a register configured to store a first unique identifier associated with a terminal in combination with identification of at least one associated grant access time interval, the at least one associated grant access time interval being a time period during which access for the terminal is permitted, the method comprising the steps of:

receiving an access request and the unique identifier from the terminal for access to the telecommunications network;

accessing the associated time period using the unique identifier;

denying the terminal access to the telecommunications network responsive to the access request being received outside the time period;

monitoring a network load of the telecommunications network; and

adapting the time period depending on the monitored network load,

wherein machine-to-machine applications are executed, and wherein the plurality of terminals for the machine-to-machine applications are denied access to the telecommunications network during peak load time intervals, the time period being outside peak load time intervals.

16. The method of claim 15, wherein the telecommunications network is a cellular network and the register is one of a home location register and a home subscriber server of the cellular network.

17. The method according to claim 15, wherein denying the terminal access to the telecommunications network comprises denying the terminal a network attach to the telecommunications network.

18. The method according to claim 15, further comprising the step of denying access of the terminal in the telecommunications network prior to authenticating the terminal.

19. The method according to claim 15, further comprising the steps of:

authenticating the terminal in the telecommunications network in response to receiving the access request; and denying the terminal a network attach in response to receiving a second access request from the terminal.

20. The method according to claim 15, further comprising the steps of:

receiving the access request to the telecommunications network at a serving controller entity;

retrieving the identification of the at least one associated grant access time interval from the register to the serving controller entity in response to receiving the access request; and

denying at least one of a network attach to the telecommunications network with the terminal or an establishment of a packet data protocol context with the terminal if the access request is received outside the time period defined by the retrieved identification of the at least one associated grant access time interval.

21. The method according to claim 15, further comprising the step of transmitting an access denial message to the terminal.

22. The method according to claim 15, further comprising the step of authenticating the terminal for access to a further network during the time period.

23. The method of claim 15, wherein the network load is one of (i) monitored in real-time or (ii) based on an expected network load.

24. The method of claim 15, wherein the plurality of terminals of the machine-to-machine applications are denied access to the telecommunications network during peak load hours, the time period being outside peak load hours.

25. The method of claim 15,

wherein each of the plurality of terminals of the machine-to-machine applications has a respective time period that is determined according to one of: (i) a respective pre-defined grant-time interval, (ii) a variable time interval scheduled based on actual network load, and (iii) a variable time interval scheduled based on an expected network load,

and wherein access to the telecommunications network is granted to a terminal of the plurality if its respective time period is one of below a particular threshold, or predicted to be below the particular threshold.

26. The method of claim 15, wherein the plurality of terminals of the machine-to-machine applications have one or more time periods assigned to a particular one or more of the plurality.

27. The method of claim 15, wherein monitoring a network load of the telecommunications network comprises obtaining network load information from a network device, the network device being one of a home location register (HLR), a low level device of the telecommunications network, or a SGSN of the network.

## 11

28. The method as recited in claim 15 wherein the telecommunications network further comprises a network load monitor and wherein:

monitoring the network load of the telecommunications network is performed by the network load monitor and further wherein:

the network obtains network load information from the home location register HLR of the telecommunications network or from a low level of the telecommunications network.

29. The method as recited in claim 28 wherein the telecommunications network is a cellular network containing a SGSN, and wherein the network load is obtained from the SGSN.

30. A tangible, non-transitory computer-readable medium having instructions stored thereon that, when executed by one or more processors of a telecommunications network device of a telecommunications network, cause the telecommunications network device to perform operations comprising:

receiving an access request and unique identifier from a terminal for access to the telecommunications network; accessing, using the unique identifier, an identification of at least one associated grant access time interval, the at least one associated grant access time interval being a time period during which access for the terminal is permitted;

denying the terminal access to the telecommunications network responsive to the access request being received outside the time period defined by the accessed identification of the at least one associated grant access time interval;

monitoring a network load of the telecommunications network;

adapting the time period depending on the monitored network load; and

denying access to the telecommunications network to one or more terminals attempting to engage in machine-to-machine applications during peak load time intervals, the time period being outside peak load time intervals.

31. A telecommunications network configured for providing access to a plurality of terminals, each terminal associated with a unique identifier for accessing the telecommunications network, wherein the telecommunications network comprises:

a register configured to store the unique identifier of at least one terminal in combination with identification of at least one associated deny access time interval, the at least one associated deny access time interval being a time period during which telecommunications network access for the terminal is denied;

one or more processors;

memory storing processor instructions that, when executed by the one or more processors, cause the one or more processors to carry out operations including:

an access request operation to receive an access request from the terminal and to receive or determine the unique identifier associated with the terminal;

an access operation to deny access for the terminal if the access request is received within the time period,

wherein the telecommunications network is further configured to monitor a network load of the telecommunications network,

wherein the telecommunications network is further configured to adapt the time period depending on the monitored network load, and

wherein machine-to-machine applications are executed, and wherein the plurality of terminals for the machine-

## 12

to-machine applications are denied access to the telecommunications network during peak load time intervals, the time period being within peak load time intervals.

32. A computer-implemented method of controlling access to a telecommunications network, the telecommunications network being configured for allowing access for a plurality of terminals, each terminal associated with a unique identifier for accessing the telecommunications network, the telecommunications network comprising a register configured to store a first unique identifier associated with a terminal in combination with at least one associated deny access time interval, the at least one associated deny access time interval being a time period during which access for the terminal is denied, the method comprising the steps of:

receiving an access request and the unique identifier from the terminal for access to the telecommunications network;

accessing the identification of at least one associated deny access time interval using the unique identifier;

denying the terminal access to the telecommunications network responsive to the access request being received within the time period defined by the accessed identification of at least one associated deny access time interval;

monitoring a network load of the telecommunications network; and

adapting the time period depending on the monitored network load,

wherein machine-to-machine applications are executed, and wherein the plurality of terminals for the machine-to-machine applications are denied access to the telecommunications network during peak load time intervals, the time period being within peak load time intervals.

33. A tangible, non-transitory computer-readable medium having instructions stored thereon that, when executed by one or more processors of a telecommunications network device of a telecommunications network, cause the telecommunications network device to perform operations comprising:

receiving an access request and unique identifier from a terminal for access to the telecommunications network; accessing, using the unique identifier, an identification of at least one associated deny access time interval, the at least one associated deny access time interval being a time period during which access for the terminal is denied;

denying the terminal access to the telecommunications network responsive to the access request being received within the time period defined by the accessed identification of at least one associated deny access time interval;

monitoring a network load of the telecommunications network;

adapting the time period depending on the monitored network load; and

denying access to the telecommunications network to one or more terminals attempting to engage in machine-to-machine applications during peak load time intervals, the time period being within peak load time intervals.

34. A terminal for use in a telecommunications network, wherein the telecommunications network is configured for providing access to a plurality of terminals, each terminal being associated with a unique identifier for accessing the telecommunications network,

wherein the terminal comprises a message receiver configured for receiving a message from the telecommunica-

**13**

tions network, the message comprising information relating to a grant access time interval, the grant access time interval being a time period during which telecommunications network access for the terminal is permitted,

wherein the time period is adapted by the telecommunications network depending on a monitored network load, and wherein the terminal further comprises one or more processors, and memory storing processor instructions that, when executed by the one or more processors, cause the one or more processors to carry out operations including:

an access request operation for transmitting an access request to the telecommunications network in accordance with the grant access time interval,

wherein machine-to-machine applications are executed in the telecommunications network, and wherein the terminal for the machine-to-machine applications are denied access to the telecommunications network during peak load time intervals, the time period being outside peak load time intervals.

**35.** A terminal for use in a telecommunications network, wherein the telecommunications network is configured for providing access to a plurality of terminals, each terminal being associated with a unique identifier for accessing the telecommunications network,

**14**

wherein the terminal comprises a message receiver configured for receiving a message from the telecommunications network, the message comprising information relating to a deny access time interval, the deny access time interval being a time period during which telecommunications network access for the terminal is denied, wherein the time period is adapted by the telecommunications network depending on a monitored network load, and wherein the terminal further comprises one or more processors, and memory storing processor instructions that, when executed by the one or more processors, cause the one or more processors to carry out operations including:

an access request operation for transmitting an access request to the telecommunications network in accordance with the deny access time interval,

wherein machine-to-machine applications are executed in the telecommunications network, and wherein the terminal for the machine-to-machine applications are denied access to the telecommunications network during peak load time intervals, the time period being within peak load time intervals.

**36.** The telecommunications network according to claim **1**, wherein the telecommunications network comprises a network load monitor configured for monitoring the network load of said telecommunications network.
